The NASA STI Office... in Profile

Since its founding, NASA has been dedicated to the advancement of aeronautics and space science. The NASA Scientific and Technical Information (STI) Office plays a key part in helping NASA maintain this important role.

The NASA STI Office provides access to the NASA STI Database, the largest collection of aeronautical and space science STI in the world. The Office is also NASA's institutional mechanism for disseminating the results of its research and development activities.

Specialized services that help round out the STI Office's diverse offerings include creating custom thesauri, building customized databases, organizing and publishing research results ... even providing videos.

For more information about the NASA STI Office, you can:

- **Phone** the NASA Access Help Desk at (301) 621-0390
- **Fax** your question to the NASA Access Help Desk at (301) 621-0134
- **E-mail** your question via the **Internet** to help@sti.nasa.gov
- **Write** to:

  NASA Access Help Desk
  NASA Center for AeroSpace Information
  800 Elkridge Landing Road
  Linthicum Heights, MD 21090-2934

Scientific and Technical Aerospace Reports

Scientific and Technical Aerospace Reports (STAR), is published each month as a major product of the NASA Scientific and Technical Information (STI) Office.

Inside this issue you will find:

- **Front Matter** containing a typical citation and abstract sample explaining the standard format, including codes for ordering reports
- **An Abstract Section** containing citations and abstracts of reports and publications that provide comprehensive coverage of worldwide aerospace-related topics including aeronautics and space science technology. *STAR* lists published and publicly available reports entered into the NASA STI Database during the four weeks preceding publication of this issue. These citations and abstracts are listed by subject categories.
- **An Index Section**
  - Subject
  - Personal author
  - Corporate source
  - Contract number
  - Report number
- **An Appendix** containing a guide for ordering cited reports, registering with the NASA STI Office, and using the available products and services. Additionally, price schedules, phone numbers, and addresses are included in this information packed section.

NASA also sponsors the companion journal, *NASA Open Volumes on Aerospace (NOVA)*, which lists abstracts of the open literature on aerospace subjects available worldwide. *NOVA* is for internal NASA use only, available from the NASA Center for AeroSpace Information (CASI).

Entries found in *STAR* are available through the NASA online retrieval service, RECON.

The NASA STI Office gathers information through national and international agreements and exchanges and makes this information available to the NASA community and to the public in many forms through various outlets.

For additional information on the NASA STI Office, call the NASA Access Help Desk at (301) 621-0390, or write to:

TABLE OF CONTENTS

AERONAUTICS For related information see also *Astronautics.*

01 AERONAUTICS (GENERAL) **2741**

02 AERODYNAMICS **2742**
Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery. For related information see also *34 Fluid Mechanics and Heat Transfer.*

03 AIR TRANSPORTATION AND SAFETY **2745**
Includes passenger and cargo air transport operations; and aircraft accidents. For related information see also *16 Space Transportation* and *85 Urban Technology and Transportation.*

04 AIRCRAFT COMMUNICATIONS AND NAVIGATION **2748**
Includes digital and voice communication with aircraft; air navigation systems (satellite and ground based); and air traffic control. For related information see also *17 Space Communications, Spacecraft Communications, Command and Tracking* and *32 Communications and Radar.*

05 AIRCRAFT DESIGN, TESTING AND PERFORMANCE **2750**
Includes aircraft simulation technology. For related information see also *18 Spacecraft Design, Testing and Performance* and *39 Structural Mechanics.* For land transportation vehicles see *85 Urban Technology and Transportation.*

06 AIRCRAFT INSTRUMENTATION **2753**
Includes cockpit and cabin display devices; and flight instruments. For related information see also *19 Spacecraft Instrumentation* and *35 Instrumentation and Photography.*

07 AIRCRAFT PROPULSION AND POWER **2753**
Includes prime propulsion systems and systems components, e.g., gas turbine engines and compressors; and onboard auxiliary power plants for aircraft. For related information see also *20 Spacecraft Propulsion and Power, 28 Propellants and Fuels,* and *44 Energy Production and Conversion.*

08 AIRCRAFT STABILITY AND CONTROL **2756**
Includes aircraft handling qualities; piloting; flight controls; and autopilots. For related information see also *05 Aircraft Design, Testing and Performance.*

09 RESEARCH AND SUPPORT FACILITIES (AIR) **2762**
Includes airports, hangars and runways; aircraft repair and overhaul facilities; wind tunnels; shock tubes; and aircraft engine test stands. For related information see also *14 Ground Support Systems and Facilities (Space).*

ASTRONAUTICS For related information see also *Aeronautics.*

12 ASTRONAUTICS (GENERAL) ..... **N.A.**
For extraterrestrial exploration see *91 Lunar and Planetary Exploration.*

13 ASTRODYNAMICS ..... **N.A.**
Includes powered and free-flight trajectories; and orbital and launching dynamics.

14 GROUND SUPPORT SYSTEMS AND FACILITIES (SPACE) ..... **N.A.**
Includes launch complexes, research and production facilities; ground support equipment, e.g., mobile transporters; and simulators. For related information see also *09 Research and Support Facilities (Air).*

15 LAUNCH VEHICLES AND SPACE VEHICLES **2764**
Includes boosters; operating problems of launch/space vehicle systems; and reusable vehicles. For related information see also *20 Spacecraft Propulsion and Power.*

16 SPACE TRANSPORTATION **2764**
Includes passenger and cargo space transportation, e.g., shuttle operations; and space rescue techniques. For related information see also *03 Air Transportation and Safety* and *18 Spacecraft Design, Testing and Performance.* For space suits see *54 Man/System Technology and Life Support.*

17 SPACE COMMUNICATIONS, SPACECRAFT COMMUNICATIONS, COMMAND AND TRACKING **2765**
Includes telemetry; space communications networks; astronavigation and guidance; and radio blackout. For related information see also *04 Aircraft Communications and Navigation* and *32 Communications and Radar.*

N.A.—No abstracts were assigned to this category for this issue.

18 SPACECRAFT DESIGN, TESTING AND PERFORMANCE **2765**
Includes satellites; space platforms; space stations; spacecraft systems and components such as thermal and environmental controls; and attitude controls. For life support systems see *54 Man/System Technology and Life Support.* For related information see also *05 Aircraft Design, Testing and Performance, 39 Structural Mechanics,* and *16 Space Transportation.*

19 SPACECRAFT INSTRUMENTATION ..... **N.A.**
For related information see also *06 Aircraft Instrumentation* and *35 Instrumentation and Photography.*

20 SPACECRAFT PROPULSION AND POWER **2768**
Includes main propulsion systems and components, e.g., rocket engines; and spacecraft auxiliary power sources. For related information see also *07 Aircraft Propulsion and Power, 28 Propellants and Fuels, 44 Energy Production and Conversion,* and *15 Launch Vehicles and Space Vehicles.*

CHEMISTRY AND MATERIALS

23 CHEMISTRY AND MATERIALS (GENERAL) **2771**

24 COMPOSITE MATERIALS **2783**
Includes physical, chemical, and mechanical properties of laminates and other composite materials. For ceramic materials see *27 Nonmetallic Materials.*

25 INORGANIC AND PHYSICAL CHEMISTRY **2791**
Includes chemical analysis, e.g., chromatography; combustion theory; electrochemistry; and photochemistry. For related information see also *77 Thermodynamics and Statistical Physics.*

26 METALLIC MATERIALS **2802**
Includes physical, chemical, and mechanical properties of metals, e.g., corrosion; and metallurgy.

27 NONMETALLIC MATERIALS **2811**
Includes physical, chemical, and mechanical properties of plastics, elastomers, lubricants, polymers, textiles, adhesives, and ceramic materials. For composite materials see *24 Composite Materials.*

28 PROPELLANTS AND FUELS **2825**
Includes rocket propellants, igniters and oxidizers; their storage and handling procedures; and aircraft fuels. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *44 Energy Production and Conversion.*

29 MATERIALS PROCESSING **2837**
Includes space-based development of products and processes for commercial application. For biological materials see *55 Space Biology:*

ENGINEERING For related information see also *Physics.*

31 ENGINEERING (GENERAL) **2838**
Includes vacuum technology; control engineering; display engineering; cryogenics; and fire prevention.

32 COMMUNICATIONS AND RADAR **2845**
Includes radar; land and global communications; communications theory; and optical communications. For related information see also *04 Aircraft Communications and Navigation* and *17 Space Communications, Spacecraft Communications, Command and Tracking.* For search and rescue see *03 Air Transportation and Safety,* and *16 Space Transportation.*

33 ELECTRONICS AND ELECTRICAL ENGINEERING **2858**
Includes test equipment and maintainability; components, e.g., tunnel diodes and transistors; microminiaturization; and integrated circuitry. For related information see also *60 Computer Operations and Hardware* and *76 Solid-State Physics.*

34 FLUID MECHANICS AND HEAT TRANSFER **2866**
Includes boundary layers; hydrodynamics; fluidics; mass transfer and ablation cooling. For related information see also *02 Aerodynamics* and *77 Thermodynamics and Statistical Physics.*

35 INSTRUMENTATION AND PHOTOGRAPHY **2878**
Includes remote sensors; measuring instruments and gauges; detectors; cameras and photographic supplies; and holography. For aerial photography see *43 Earth Resources and Remote Sensing.* For related information see also *06 Aircraft Instrumentation* and *19 Spacecraft Instrumentation.*

36 LASERS AND MASERS **2882**
Includes parametric amplifiers. For related information see also *76 Solid-State Physics.*

37 MECHANICAL ENGINEERING **2887**
Includes auxiliary systems (nonpower); machine elements and processes; and mechanical equipment.

38 QUALITY ASSURANCE AND RELIABILITY **2891**
Includes product sampling procedures and techniques; and quality control.

39 STRUCTURAL MECHANICS **2892**
Includes structural element design and weight analysis; fatigue; and thermal stress. For applications see *05 Aircraft Design, Testing and Performance* and *18 Spacecraft Design, Testing and Performance.*

GEOSCIENCES For related information see also *Space Sciences.*

42 GEOSCIENCES (GENERAL) **2899**

43 EARTH RESOURCES AND REMOTE SENSING **2900**
Includes remote sensing of earth resources by aircraft and spacecraft; photogrammetry; and aerial photography. For instrumentation see *35 Instrumentation and Photography.*

44 ENERGY PRODUCTION AND CONVERSION **2902**
Includes specific energy conversion systems, e.g., fuel cells; global sources of energy; geophysical conversion; and windpower. For related information see also *07 Aircraft Propulsion and Power, 20 Spacecraft Propulsion and Power,* and *28 Propellants and Fuels.*

45 ENVIRONMENT POLLUTION **2907**
Includes atmospheric, noise, thermal, and water pollution.

46 GEOPHYSICS **2912**
Includes aeronomy; upper and lower atmosphere studies; ionospheric and magnetospheric physics; and geomagnetism. For space radiation see *93 Space Radiation.*

47 METEOROLOGY AND CLIMATOLOGY **2918**
Includes weather forecasting and modification.

48 OCEANOGRAPHY **2922**
Includes biological, dynamic, and physical oceanography; and marine resources. For related information see also *43 Earth Resources and Remote Sensing.*

LIFE SCIENCES

51 LIFE SCIENCES (GENERAL) **2925**

52 AEROSPACE MEDICINE **2926**
Includes physiological factors; biological effects of radiation; and effects of weightlessness on man and animals.

53 BEHAVIORAL SCIENCES **2928**
Includes psychological factors; individual and group behavior; crew training and evaluation; and psychiatric research.

54 MAN/SYSTEM TECHNOLOGY AND LIFE SUPPORT **2929**
Includes human engineering; biotechnology; and space suits and protective clothing. For related information see also *16 Space Transportation.*

55 SPACE BIOLOGY ..... **N.A.**
Includes exobiology; planetary biology; and extraterrestrial life.

MATHEMATICAL AND COMPUTER SCIENCES

59 MATHEMATICAL AND COMPUTER SCIENCES (GENERAL) **2931**

60 COMPUTER OPERATIONS AND HARDWARE **2931**
Includes hardware for computer graphics, firmware, and data processing. For components see *33 Electronics and Electrical Engineering.*

61 COMPUTER PROGRAMMING AND SOFTWARE **2932**
Includes computer programs, routines, algorithms, and specific applications, e.g., CAD/CAM.

62 COMPUTER SYSTEMS **2947**
Includes computer networks and special application computer systems.

63 CYBERNETICS **2949**
Includes feedback and control theory, artificial intelligence, robotics and expert systems. For related information see also *54 Man/System Technology and Life Support.*

64 NUMERICAL ANALYSIS **2954**
Includes iteration, difference equations, and numerical approximation.

65 STATISTICS AND PROBABILITY **2963**
Includes data sampling and smoothing; Monte Carlo method; and stochastic processes.

66 SYSTEMS ANALYSIS **2964**
Includes mathematical modeling; network analysis; and operations research.

67 THEORETICAL MATHEMATICS **2964**
Includes topology and number theory.

PHYSICS For related information see also *Engineering.*

The effects of a forward-swept front rotor on the flowfield of a counterrotation model propeller at takeoff conditions at zero degree angle of attack are studied by solving the unsteady three-dimensional Euler equations. The configuration considered is an uneven blade count counterrotation model with twelve forward-swept blades on the fore rotor and ten aft-swept blades on the aft rotor. The flowfield is compared with that of a reference aft-swept counterrotation geometry and Laser Doppler Velocimeter (LDV) measurements. At the operating conditions considered, the forward-swept blade experiences a higher tip loading and produces a stronger tip vortex compared to the aft-swept blade, consistent with the LDV and acoustic measurements. Neither the solution nor the LDV data indicated the formation of a leading edge vortex. The predicted radial distribution of the circumferentially averaged axial velocity at the measurement station agreed very closely with LDV data, while crossflow velocities showed poor agreement. The discrepancy between prediction and LDV data of tangential and radial velocities is due in part to the insufficient mesh resolution in the region between the rotors and in the tip region to track the tip vortex. The vortex is diffused by the time it arrives at the measurement station. The uneven blade count configuration requires the solution to be carried out for six blade passages of the fore rotor and five passages of the aft rotor, thus making grid refinement prohibitive.

Scientific and Technical Aerospace Reports

A Monthly Publication of the National Aeronautics and Space Administration

01 AERONAUTICS (GENERAL)

N95-31000*# National Aeronautics and Space Administration. Langley Research Center, Hampton, VA.
PATTERNS IN THE SKY: NATURAL VISUALIZATION OF AIRCRAFT FLOW FIELDS
James F. Campbell and Joseph R. Chambers 1994 162 p Original contains color illustrations
(NASA-SP-514; NAS 1.21:514) Avail: CASI HC A08/MF A02; 118 functional color pages

The objective of the current publication is to present the collection of flight photographs to illustrate the types of flow patterns that were visualized and to present qualitative correlations with computational and wind tunnel results. Initially in section 2, the condensation process is discussed, including a review of relative humidity, vapor pressure, and factors which determine the presence of visible condensate. Next, outputs from computer code calculations are postprocessed by using water-vapor relationships to determine if computed values of relative humidity in the local flow field correlate with the qualitative features of the in-flight condensation patterns. The photographs are then presented in section 3 by flow type and subsequently in section 4 by aircraft type to demonstrate the variety of condensed flow fields that was visualized for a wide range of aircraft and flight maneuvers. FAA AVIATION FORECASTS: FISCAL YEAR 1995-2006
Mar. 1995 243 p
(AD-A293682; FAA-APO-95-1) Avail: CASI HC A11/MF A03

This report contains the Fiscal Years 1995-2006 Federal Aviation Administration (FAA) forecasts of aviation activity at FAA facilities. These include airports with FAA control towers, air route traffic control centers, and flight service stations. Detailed forecasts were made for the major users of the National Aviation System: air carriers, air taxi/ commuters, military, and general aviation. The forecasts have been prepared to meet the budget and planning needs of the constituent units of the FAA and to provide information that can be used by state and local authorities, the aviation industry, and the general public. The outlook for the 12-year forecast period is for moderate economic growth, stable real fuel prices, modest inflation, and continued moderate to strong growth in the demand for aviation services. Based on these assumptions, aviation activity is forecast to increase by 19.7 percent at FAA towered airports (352 airports) and 26.0 percent at air route traffic control centers. The general aviation active fleet is forecast to decline by 0.8 percent during the forecast period but increased utilization (hours flown by aircraft) results in a 12.0 percent increase in general aviation hours flown during same period. Scheduled domestic revenue passenger miles (RPM's) are forecast to increase 60.5 percent, scheduled international RPM's are forecast to increase by 97.2 percent, and regional/commuter RPM's are forecast to increase by 154.1 percent. MAPPING HIDDEN AIRCRAFT DEFECTS WITH DUAL-BAND INFRARED COMPUTED TOMOGRAPHY
Nancy K. DelGrande and Philip F. Durbin 3 Apr. 1995 14 p Presented at the Conference on Nondestructive Evaluation of Aging Infrastructure, Oakland, CA, 6-8 Jun. 1995
(Contract W-7405-eng-48)
(DE95-011531; UCRL-JC-120546; CONF-9506126-2) Avail: CASI HC A03/MF A01

Infrared computed tomography (IRCT) is a promising, non-contact, nondestructive evaluation tool used to inspect the mechanical integrity of large structures. We describe on-site, proof-of-principle demonstrations of IRCT to inspect defective metallic and composite structures. The IRCT system captures time sequences of heat-stimulated, dual-band infrared (DBIR) thermal maps for flash-heated and naturally-heated targets. Our VIEW algorithms produce co-registered thermal, thermal inertia, and thermal-timegram maps from which we quantify the percent metal-loss corrosion damage for airframes and the defect sites, depths, and host-material physical properties for composite structures. The IRCT method clarifies the type of defect, e.g., corrosion, fabrication, foreign-material insert, delamination, unbond, void, and quantifies the amount of damage from the defect, e.g., the percent metal-loss from corrosion in metal structures, the depth, thickness, and areal extent of heat damage in multi-layered composite materials. Potential long-term benefits of IRCT technology are in-service monitoring of incipient corrosion damage, to avoid catastrophic failure and production-monitoring of cure states for composite materials. REPORT TO THE CHAIRMAN, LEGISLATION AND NATIONAL SECURITY SUBCOMMITTEE, COMMITTEE ON GOVERNMENT OPERATIONS, HOUSE OF REPRESENTATIVES. C-17 AIRCRAFT PROGRAM: IMPROVEMENTS IN INITIAL PROVISIONING PROCESS
21 Jan. 1994 11 p
(GAO/NSIAD-94-63; B-255832) Avail: CASI HC A03/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20877 HC

This GAO report is an updated review of the Air Force's initial provisioning of spare parts for the C-17 military transport aircraft. Since 1989, when it began initial provisioning for the C-17 aircraft program, the Air Force has frequently ordered spare parts prematurely. As of July 1993, the Air Force had $111.2 million of C-17 spare parts on order. These premature procurements were made under a DOD policy that called for maximizing procurement of support items for the provisioning period. Within the framework of this policy, this report finds that premature ordering occurred because the Air Force: used inaccurate and outdated information to determine how many spare parts to buy and when to buy them; bought quantities of spare parts that were higher than computed stockage levels justified; and failed to follow regulations that governed the initial provisioning process. DOD has recently revised its provisioning guidance to stress the need to limit the initial procurement of spare parts, thereby minimizing cost. Derived from text

N95-32198# General Accounting Office, Washington, DC. National Security and International Affairs Div.
REPORT TO CONGRESSIONAL COMMITTEES. MILITARY AIRLIFT: C-17 SETTLEMENT IS NOT A GOOD DEAL
15 Apr. 1994 18 p
(GAO/NSIAD-94-141; B-256721) Avail: CASI HC A03/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20877 HC

This report deals with the status of the C-17 program, with emphasis on DoD's proposed settlement agreement with McDonnell Douglas, the prime contractor on the C-17 aircraft. It also discusses DOD's efforts to identify alternatives to the C-17 program. Rising program costs, less than anticipated performance, and lengthy delays in this concurrent acquisition

program raise serious doubts about the C-17's cost-effectiveness and undermine the program's credibility. Despite these problems, DOD has proposed a settlement with McDonnell Douglas that, in our opinion, is not in the best interest of the government. Although the true cost is not known, the settlement identifies the cost to the government and the contractor as $348 million and $454 million, respectively. Under the proposed settlement, DOD would delay the decision on the number of C-17's to be procured until November 1995; it would also, in effect, delay the decision on the most cost-effective mix of aircraft for meeting its airlift requirements until that time. Most of the benefits of the contractor's management and productivity improvements called for in the settlement will not be realized until 1996 or beyond. We are also concerned that DOD has not established specific cost, schedule, and performance criteria to evaluate McDonnell Douglas' performance and to decide whether to purchase more than 40 aircraft. CASI

02 AERODYNAMICS

Includes aerodynamics of bodies, combinations, wings, rotors, and control surfaces; and internal flow in ducts and turbomachinery.

FLOW MODELS FOR THE DESIGN OF A HYPERSONIC IODINE VAPOR WIND TUNNEL NOZZLE WITH CHEMICAL AND VIBRATIONAL NONEQUILIBRIUM EFFECTS Ph.D. Thesis
Marty Keith Bradley 1994
Avail: Issuing Activity (Univ. of Southern California, Doheny Library, Micrographics Dept., Los Angeles, CA 90089-0182)

A hypersonic iodine wind tunnel facility (H.I.T.) is being built at the University of Southern California (U.S.C.) to study hypersonic nonequilibrium flow. A detailed model for iodine nozzle flow with vibrational as well as chemical nonequilibrium has been developed to assess the impact of vibrational nonequilibrium in the wind tunnel nozzle. Each discrete vibrational level is treated as a separate species and reaction rate expressions are developed for vibration-vibration (V-V), vibration-translation (V-T), and dissociation reactions using various reaction rate models. Vibrational equilibrium, harmonic oscillator, SSH, and modified SSH thermodynamic and reaction rate models have been developed for iodine. One-dimensional and two-dimensional finite-rate chemistry nozzle calculations have been made using the LPP (Liquid Performance Program) nozzle analysis code. In the SSH and modified SSH models, V-T transitions were found to be dominant when compared to V-V transitions, and population inversions were created downstream in the nozzle in vibrational levels above about ten for the harmonic oscillator, SSH, and modified SSH models. Results from these calculations have been compared to data from an iodine freejet test. The sensitivity of the wind tunnel nozzle exit flow profile to the various nonequilibrium flow models has also been determined. Based on these results and considering the effects of vibrational nonequilibrium and boundary layer state, a nozzle contour has been designed that will produce near-uniform flow properties for the first H.I.T. nozzle, despite any uncertainties present in the chemistry, vibration, or boundary layer flow models. DEVELOPMENT OF A LINEARIZED UNSTEADY EULER ANALYSIS FOR TURBOMACHINERY BLADE ROWS Final Contractor Report
Joseph M. Verdon, Matthew D. Montgomery, and Kenneth A. Kousen Jun. 1995 107 p
(Contract NAS3-25425; RTOP 505-62-10)
(NASA-CR-4677; E-9575; NAS 1.26:4677; R95-970293) Avail: CASI HC A06/MF A02

A linearized unsteady aerodynamic analysis for axial-flow turbomachinery blading is described in this report. The linearization is based on the Euler equations of fluid motion and is motivated by the need for an efficient aerodynamic analysis that can be used in predicting the aeroelastic and aeroacoustic responses of blade rows. The field equations and surface conditions required for inviscid, nonlinear and linearized, unsteady aerodynamic analyses of three-dimensional flow through a single, blade row operating within a cylindrical duct, are derived. An existing numerical algorithm for determining time-accurate solutions of the nonlinear unsteady flow problem is described, and a numerical model, based upon this nonlinear flow solver, is formulated for the first-harmonic linear unsteady problem. The linearized aerodynamic and numerical models have been implemented into a first-harmonic unsteady flow code, called LINFLUX. At present this code applies only to two-dimensional flows, but an extension to three-dimensions is planned as future work. The three-dimensional aerodynamic and numerical formulations are described in this report. Numerical results for two-dimensional unsteady cascade flows, excited by prescribed blade motions and prescribed aerodynamic disturbances at inlet and exit, are also provided to illustrate the present capabilities of the LINFLUX analysis. AXIAL LOADS ON YAWED ROTORS
G. J. W. vanBussel Nov. 1993 28 p
(PB95-214193; IW-93073R) Avail: CASI HC A03/MF A01

Under the assumption of incompressible, inviscid and irrotational flow, it can be shown that the pressure perturbation in the complete flow field is given by a Laplace equation and acts as an acceleration potential function. The rotor blades are represented in the model as discrete surfaces on which a pressure discontinuity is present. Spanwise and chordwise pressure distributions are present, which are composed of analytical asymptotic solutions for the Laplace equation. This model is implemented in the PREDICHAT and PREDICDYN computer code series for steady and dynamic inflow cases respectively. Dynamic inflow concerns with large scale unsteady rotor aerodynamics, such as coherent wind gusts, collective blade pitch and rotor speed variations. PREDICDYN is at present extended for the investigation of yawed flow. Axial induction velocities and axial load distributions are determined with this method and compared with yawed flow momentum theory extensions. NTIS

VALIDATION OF THE NPARC CODE FOR NOZZLE AFTERBODY FLOWS AT TRANSONIC SPEEDS
James R. DeBonis, Nicholas J. Georgiadis, and Crawford F. Smith (NYMA, Inc., Brook Park, OH.) Jul. 1995 28 p Presented at the 31st Joint Porpulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; sponsored by AIAA, ASME, SAE, and ASEE
(Contract NAS3-27186; RTOP 537-02-00)
(NASA-TM-106971; E-9732; NAS 1.15:106971; AIAA Paper 95-2614)
Avail: CASI HC A03/MF A01

The NPARC code, a Reynolds-averaged full Navier-Stokes code, was validated for nozzle afterbody (boatail) flow fields at transonic speeds. The flow fields about three geometries were studied: an axisymmetric nozzle with attached flow; an axisymmetric nozzle with separated flow: and a two-dimensional (rectangular) nozzle with separated flow. Three turbulence models, Baldwin-Lomax, Baldwin-Barth, and Chien k-epsilon, were used to determine the effect of turbulence model selection on the flow field solution. Static pressure distributions on the nozzle surfaces and pitot pressure measurements in the exhaust plume were examined. Results from the NPARC code compared very well with experimental data for all cases. For attached flow fields, the effect of the turbulence models showed no discernable differences. The Baldwin-Barth model yielded better results than either the Chien k-epsilon or the Baldwin-Lomax model for separated flow fields. Author

TRANSONIC AERODYNAMIC CHARACTERISTICS OF A PROPOSED WING-BODY REUSABLE LAUNCH VEHICLE CONCEPT
A. M. Springer Washington Mar. 1995 111 p
(NASA-TM-108489; NAS 1.15:108489) Avail: CASI HC A06/MF A02

A proposed wing-body reusable launch vehicle was tested in the NASA Marshall Space Flight Center's 14 x 14-inch trisonic wind tunnel during the winter of 1994. This test resulted in the vehicle's subsonic and transonic, Mach 0.3 to 1.96, longitudinal and lateral aerodynamic characteristics. The effects of control surface deflections on the basic vehicle's aerodynamics, including a body flap, elevons, ailerons, and tip fins, are presented. Author

FLIGHT TEST EVALUATION OF THE STANFORD UNIVERSITY/UNITED AIRLINES DIFFERENTIAL GPS CATEGORY 3 AUTOMATIC LANDING SYSTEM

David N. Kaufmann and B. David NcNally Jun. 1995 475 p
(RTOP 505-64-13)
(NASA-TM-110354; A-950066; NAS 1.15:110354) Avail: CASI HC A20/MF A04

Test flights were conducted to evaluate the capability of Differential Global Positioning System (DGPS) to provide the accuracy and integrity required for International Civil Aviation Organization (ICAO) Category (CAT) 3 precision approach and landings. These test flights were part of a Federal Aviation Administration (FAA) program to evaluate the technical feasibility of using DGPS based technology for CAT 3 precision approach and landing applications. A United Airlines Boeing 737-300 (N304UA) was equipped with DGPS receiving equipment and additional computing capability provided by Stanford University. The test flights were conducted at NASA Ames Research Center's Crows Landing Flight Facility, Crows Landing, California. The flight test evaluation was based on completing 100 approaches and autolandings; 90 touch and go, and 10 terminating with a full stop. Two types of accuracy requirements were evaluated: 1) Total system error, based on the Required Navigation Performance (RNP), and 2) Navigation sensor error, based on ICAO requirements for the Microwave Landing System (MLS). All of the approaches and autolandings were evaluated against ground truth reference data provided by a laser tracker. Analysis of these approaches and autolandings shows that the Stanford University/United Airlines system met the requirements for a successful approach and autolanding 98 out of 100 approaches and autolandings, based on the total system error requirements as specified in the FAA CAT 3 Level 2 Flight Test Plan. NUMERICAL INVESTIGATION INTO VORTICAL FLOW ABOUT A DELTA-WING CONFIGURATION UP TO INCIDENCES AT WHICH VORTEX BREAKDOWN OCCURS IN EXPERIMENT

J. I. vandenBerg, H. W. M. Hoeijmakers, and F. J. Brandsma 11 Nov. 1993 21 p
(Contract NIVR-07302N)
(PB95-198024; NLR-TP-93511-U) Copyright Avail: CASI HC A03/MF A01

To contribute to the development and validation of Euler methods for complete fighter configurations, numerical investigations are carried out into the flow for two generic configurations. Results are presented about a wing-alone and a wing-body configuration with a sharp-edged cropped delta wing for incidences in the range at which vortex breakdown occurs in experiment. Above the aft part of the wing-alone configuration, the structure of the vortex core undergoes a remarkable change, i.e., there is a switch-over in the sign of the vorticity vector as well as a sharp reduction of the axial velocity component, in a way similar to what occurs during vortex breakdown in experiment. For the wing-body configuration similar flow features are found, but only in the near wake. NTIS

COMPUTATION OF HIGH-ALTITUDE HYPERSONIC FLOW-FIELD RADIATION Ph.D. Thesis

Stephane Moreau 1994 438 p
Avail: Univ. Microfilms Order No. DA9422110

Accurate calculations of radiation on and from transatmospheric flight vehicles are currently a challenge to computational aerodynamicists. Due to combined effects of low density and hypersonic flight conditions, the gas in the shock-layer is in a state of thermal and chemical nonequilibrium. The present work aims at gathering existing ideas together about how such flows should be modeled and comparing them to recent, more accurate experiments that probe the separate energy modes of the different species of the gas in a more direct way than previously reported. Two recent Bow-Shock-Ultra-Violet flight experiments, and two recent shock-tube experiments are used to test the validity of the flow-field models implemented in the current state-of-the-art numerical codes. They involve highly non-equilibrium flow regimes in nitrogen and air with negligible ionization and provide detailed spectra emitted by the hot gas. A recent plasma torch experiment at Stanford, and the Cochise experiments at the Geophysics Directorate laboratories, have been the ideal experimental counterpart to test and improve the radiation calculation in the UV-visible spectral range and the IR region respectively. Each spectral region is used to probe several different aspects of the thermal and chemical nonequilibrium. A hierarchy of flow-field codes has been developed in conjunction with a greatly enhanced radiation code, termed NEQAIR2, to simulate these experiments. The flow-field codes involve axisymmetric Navier-Stokes and Burnett simulations around blunt-nose cones for the flight experiments and quasi-ID Euler simulations for the shock-tube experiments. They include between 5 and 8 chemical species and between 3 and 6 separate internal energy modes. The corresponding system of conservation equations are solved with finite volume, flux split algorithms. Gauss-Siedel line relaxation is used to increase efficiency of the fully-implicit method and exact numerical jacobians have been derived to increase the rate of convergence. The radiation code involves a collisional-radiative model based on a quasi-steady-state (QSS) approximation and a detailed line-by-line calculation for several atomic systems and molecular band systems. Comparisons of numerical spectra with the flight data show good agreement at the lower altitudes but the predictions are only within an order of magnitude at higher altitudes. Dissert. Abstr.

(Contract F33657-84-C-0247)
(AD-A293113; NLR-CR-93570L; WL-TR-94-3094) Avail: CASI HC A05/MF A01

A wind tunnel investigation was conducted in 1992 to investigate the unsteady aerodynamic aspects of transonic high incidence flows over a simple straked wing model. This test was designed to show how low speed vortex type flows evolve into complicated shock vortex interacting flows at transonic speeds. Requirements for this test were based on a low speed test conducted in 1986 on a full span model in the NLR Low Speed Tunnel. The transonic model was a semispan version of the low speed model with some modifications. It was equipped with a three-component semispan balance to measure total wing loads, seven rows of high response pressure transducers to measure unsteady pressures, and 15 vertical accelerometers to measure model motion and vibrations. The model was oscillated sinusoidally in pitch at various amplitudes and frequencies for mean model incidences varying from 4 to 48 deg. In addition, maneuver type transient motions of the model were tested with amplitudes of 16 and 30 deg total rotation at various starting angles. The test was conducted in the NLR HST in the Mach range of 0.225 to 0.90 with some preliminary vapor screen flow visualization data taken at M = 0.6 and 0.9. This part of the report presents a description of the model, test setup, data acquisition, and data processing. DTIC

HYPERVELOCITY WIND TUNNEL NUMBER 9, HIGH MACH NUMBER DEVELOPMENT PROGRAM Final Report

Melissa A. Lederer 5 Dec. 1994 85 p
(AD-A289934; NSWCDD/TR-94/96) Avail: CASI HC A05/MF A01

This report describes the results of the high Mach Number Development program performed at the White Oak, Maryland site of the Dahlgren Division, Naval Surface Warfare Center. The goal of this program was to expand the capabilities of the Hypervelocity Wind Tunnel Number 9 (Tunnel 9) to include operation at Mach 18. The constraints of this program involved

using the existing Mach 14 setup with as little modification as necessary. There were two major areas of interest for this program, the heater and the nozzle. The required supply temperature for Mach 18 operation is above the current capabilities of the Tunnel 9 Mach 14 heater. Utilizing supercooled flow conditions lowered the required supply temperature to within the Mach 14 heater capability. The current Mach 14 nozzle was used and the throat section was replaced with a new hardware set designed to achieve the correct nozzle throat-to-exit area ratio to obtain the higher Mach number. Forty-one runs were carried out in Tunnel 9 in support of this program. The Mach number capability in Tunnel 9 has been extended to Mach 16.5. For this condition the flow has a 30-inch test core with Pitot pressure deviations of -1.1% to + 1.3% and 3.5 seconds of good run time. A Mach 18 capability has also been investigated. Research efforts to achieve acceptable Mach 18 conditions are continuing. DTIC

EFFECTS OF CAVITY BLEED AND ITS CONFIGURATION ON AERODYNAMIC CHARACTERISTICS OF SUPERSONIC INTERNAL FLOW
Akira Murakami, Sigemi Shindo, Fumio Komiyama (Japanese Patent Office, Tokyo, Japan.), and Kimio Sakata Sep. 1994 18 p In JAPANESE Original contains color illustrations
(ISSN 0389-4010)
(NAL-TR-1247) Avail: CASI HC A03/MF A01

This paper presents experimental results of the effects of cavity bleed and its configuration on the supersonic internal flow field and the aerodynamic characteristics. The experiments were conducted in the supersonic heat transfer test facility of NAL using the partial model to simulate the supersonic internal compression passage of the mixed compression air-intake. The pressure recovery characteristics of five cavity configurations was obtained for the bleed mass flow rates. It was found that the cavity bleed was effective for the starting of the air-intake but the excessive cavity bleed aggravated the pressure recovery. The cavity configuration affected the characteristics of the pressure in the cavity bleed plenum for the bleed mass flow rates. Therefore, the optimum bleed mass flow rates for the maximum pressure recovery depended on the cavity configuration. Author

SIDE FORCE ACTING ON BLUNTED CIRCULAR CYLINDER BODIES AT HIGH ANGLES OF ATTACK IN SUPERSONIC FLOW
Atsushi Tate, Mitsunori Watanabe, Junichi Noda, Hideo Sekine, and Takashi Yoshinaga Dec. 1994 22 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1255) Avail: CASI HC A03/MF A01

To obtain data for stable recovery of future rocket boosters and the rocket itself, measurements of side force acting on blunted circular cylinders were carried out at high angles of attack (alpha less than 32 deg) in supersonic flows of several Mach numbers. The blunted circular heads, including a flat face and semi-elliptic shapes, were tested to determine the effects of nose shapes on side force. Highly blunted bodies close to a flat-faced cylinder show large side force as the Mach number decreases, while a flat-faced cylinder shows large side force in the narrow regions between M(sub infinity) = 1.75 and 2.25. AFTERBODY/NOZZLE PRESSURE DISTRIBUTIONS OF A TWIN-TAIL TWIN-ENGINE FIGHTER WITH AXISYMMETRIC NOZZLES AT MACH NUMBERS FROM 0.6 TO 1.2
David J. Wing May 1995 214 p
(RTOP 505-59-30-04)
(NASA-TP-3509; L-17438; NAS 1.60:3509) Avail: CASI HC A10/MF A03

Distributions of static pressure coefficient over the afterbody and axisymmetric nozzles of a generic, twin-tail twin-engine fighter were obtained in the Langley 16-Foot Transonic Tunnel. The longitudinal positions of the vertical and horizontal tails were varied for a total of six aft-end configurations. Static pressure coefficients were obtained at Mach numbers between 0.6 and 1.2, angles of attack between 0 deg and 8 deg, and nozzle pressure ratios ranging from jet-off to 8. The results of this investigation indicate that the influence of the vertical and horizontal tails extends beyond the vicinity of the tail-afterbody juncture. The pressure distribution affecting the aft-end drag is influenced more by the position of the vertical tails than by the position of the horizontal tails. Transonic tail-interference effects are seen at lower free-stream Mach numbers at positive angles of attack than at an angle of attack of 0 deg. Author

NUMERICAL SOLUTION OF THE FULL POTENTIAL EQUATION USING A CHIMERA GRID APPROACH
Terry L. Holst Jul. 1995 33 p
(RTOP 505-59-53)
(NASA-TM-110360; A-950082; NAS 1.15:110360) Avail: CASI HC A03/MF A01

A numerical scheme utilizing a chimera zonal grid approach for solving the full potential equation in two spatial dimensions is described. Within each grid zone a fully-implicit approximate factorization scheme is used to advance the solution one interaction. This is followed by the explicit advance of all common zonal grid boundaries using a bilinear interpolation of the velocity potential. The presentation is highlighted with numerical results simulating the flow about a two-dimensional, nonlifting, circular cylinder. For this problem, the flow domain is divided into two parts: an inner portion covered by a polar grid and an outer portion covered by a Cartesian grid. Both incompressible and compressible (transonic) flow solutions are included. Comparisons made with an analytic solution as well as single grid results indicate that the chimera zonal grid approach is a viable technique for solving the full potential equation. Author

CONTROL OF UNSTEADY SEPARATED FLOW ASSOCIATED WITH THE DYNAMIC STALL OF AIRFOILS Final Report
M. C. Wilder 31 Jan. 1995 41 p Original contains color illustrations
(Contract NCC2-637)
(NASA-CR-198972; NAS 1.26:198972; MCAT-95-09) Avail: CASI HC A03/MF A01; 1 functional color page

An effort to understand and control the unsteady separated flow associated with the dynamic stall of airfoils was funded for three years through the NASA cooperative agreement program. As part of this effort a substantial data base was compiled detailing the effects various parameters have on the development of the dynamic stall flow field. Parameters studied include Mach number, pitch rate, and pitch history, as well as Reynolds number (through two different model chord lengths) and the condition of the boundary layer at the leading edge of the airfoil (through application of surface roughness). It was found for free stream Mach numbers as low as 0.4 that a region of supersonic flow forms on the leading edge of the suction surface of the airfoil at moderate angles of attack. The shocks which form in this supersonic region induce boundary-layer separation and advance the dynamic stall process. Under such conditions a supercritical airfoil profile is called for to produce a flow field having a weaker leading-edge pressure gradient and no leading-edge shocks. An airfoil having an adaptive-geometry, or dynamically deformable leading edge (DDLE), is under development as a unique active flow-control device. The DDLE, formed of carbon-fiber composite and fiberglass, can be flexed between a NACA 0012 profile and a supercritical profile in a controllable fashion while the airfoil is executing an angle-of-attack pitch-up maneuver. The dynamic stall data were recorded using point diffraction interferometry (PDI), a noninvasive measurement technique. A new high-speed cinematography system was developed for recording interferometric images. The system is capable of phase-locking with the pitching airfoil motion for real-time documentation of the development of the dynamic stall flow field. Computer-aided image analysis algorithms were developed for fast and accurate reduction of the images, improving interpretation of the results. Author

FLIGHT VEHICLE INTEGRATION PANEL WORKSHOP ON PILOT INDUCED OSCILLATIONS [ATELIER SUR LE POMPAGE PILOTE]

Feb. 1995 117 p Workshop on Pilot Induced Oscillations of the Symposium on Active Control Technology, Turin, Italy, May 1994 (AGARD-AR-335; ISBN-92-836-1013-X) Copyright Avail: CASI HC A06/MF A02

Instability of the pilot/airframe combination has been a problem of manned flight. Rapid advances made in aviation following World War 2 greatly increased the incidence of PIO problems and the amount of research and development work aimed at understanding and mitigating these difficulties. Criteria and requirements were developed to be used in design to obtain satisfactory PIO qualities, but, in spite of all this work and the great flexibility in available modern control design technologies, PIO problems still often occur with new aircraft. It is clear that a universal solution of the PIO problem still evades the engineering community. The cost of these problems financially and in program delay is significant. This AGARD Flight Mechanics Workshop summary report contains presentations and discussions that aim toward the elimination and avoidance of PIO's by increasing the knowledge of PIO's and the problems associated with them. For individual titles, see N95-31062 through N95-31072.

PIO: A HISTORICAL PERSPECTIVE

Duane T. McRuer (Systems Technology, Inc., Manhatten Beach, CA.) and R. E. Smith *In* Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations Feb. 1995 4 p (For primary document see N95-31061 11-03)

Copyright Avail: CASI HC A01/MF A02

These problems relating to Pilot Induced Oscillations have manifested themselves since the earliest days of manned flight. The earliest recorded examples of PIO date back to the Wright brothers first aircraft. The earliest filmed records date back to just prior to World War 2, with the XB-19 aircraft which suffered a pitch PIO just prior to touchdown. Four classes of PIO have been identified, into which all of the known incidents can be grouped. These are: (1) Essentially Single Axis, Extended Rigid Body Effective Vehicle Dynamics; (2) Essentially Single Axis, Extended Rigid Body with Significant Feel-Systern Manipulator Mechanical Control Elements; (3) Multiple Axis, Extended Rigid Body Effective Vehicle Dynamics; and (4) PIO's Involving Higher Frequency Modes. THE PROCESS FOR ADDRESSING THE CHALLENGES OF AIRCRAFT PILOT COUPLING

Ralph AHarrah *In* Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations Feb. 1995 3 p (For primary document see N95-31061 11-03)

Copyright Avail: CASI HC A01/MF A02

The term 'Pilot Induced Oscillation' is misleading in that it places an undue emphasis on the role of the pilot in the process. Clearly, the phenomenon cannot occur in the absence of the pilot, but the term PIO suggests that the pilot is in some way responsible for the occurrence. He is not. The phenomenon may be better described by the title 'Aircraft-Pilot Coupling', or A-PC. This may be considered to better describe what is actually occurring when the pilot is trying to perform his normal function, i.e., that of controlling the aircraft which he is flying. For a designer, the objective should be to ensure that there is no possibility of A-PC occurring. Associated with this, the goal should also be to achieve Level 1 handling qualities. The key is to understand the Process involved in design and test and to ensure that this is exercised to achieve the objective. This has to be set alongside the management goals of better, faster and cheaper, in order that the manufacturer can remain competitive in the market. Derived from text

OBSERVATIONS ON PIO

Ralph H. Smith *In* Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations Feb. 1995 9 p (For primary document see N95-31061 11-03)

Copyright Avail: CASI HC A02/MF A02

Comparison of the handling characteristics of a Porsche with those expected from a modern combat type aircraft indicate that we accept significantly poorer handling performance with the aircraft than we would with a high performance road vehicle. The work which led to the evolution of the Smith-Geddes criteria stems from work performed for the USAF in relation to the F-15 aircraft. The logic that arrived at the criteria stemmed from a belief that the existing handling qualities criteria were inadequate for assessing the Pilot Induced Oscillation (PIO) susceptibility of an aircraft, and that the only successful way to test for this was to use the methods of Handling Qualities During Tracking (HQDT). The work which was performed was offered for the update of Mil 1797, but was not incorporated. This presentation concentrated on the understanding of PIO and the process by which it originates, using a simple model to demonstrate the characteristics which are inherent. The presentation also provided an explanation of the Smith-Geddes criteria, without resorting to the detail of the theories which support the criteria. The major thrust relates to the application to the assessment of PIO susceptibility and includes a commentary on the state of the control law development, together with the associated flight test technology. UNIFIED CRITERIA FOR ACT AIRCRAFT LONGITUDINAL DYNAMICS c05

Roger H. Hoh *In* Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations Feb. 1995 9 p (For primary document see N95-31061 11-03)

Copyright Avail: CASI HC A02/MF A02

This paper reports research done by USAF to adequately predict the susceptibility to pilot induced oscillation (PIO) and AGARD's response to the research. It discusses different criteria and characteristics that help to analyze PIO: the concept of phase delay, triggers, the effects of rate limiting, response characteristics and appropriate analysis techniques, and feel system influence. From the evidence presented by USAF, AGARD concludes that there is sufficient evidence that a PIO could be predicted, as could the effects of the bobweight. However, the impact of the actuation behavior may have had a dominant effect on the overall behavior of the aircraft. CASI

Eighteen years after the Tornado PIO (Pilot induced Oscillation) was successfully resolved, it seems inexplicable that similar PIO problems can still occur. For whatever reason, current formal methods are not working. The Vista F-16 is a powerful tool which should be put to use in establishing a universally acceptable set of criteria for the prevention of PIO by design. It should do this by determining the PIO qualities of a sufficiently wide range of linear and non-linear dynamic qualities, both in pitch and in roll, to establish a customer-defined set of Level boundary limits on whatever parameters are found best to quantify PIO. Only by doing this will it be possible to resolve the claims of the many competing criteria and guarantee a PIO-free future for all. It is not particularly difficult to identify the means. THE RELATION OF HANDLING QUALITIES RATINGS TO AIRCRAFT SAFETY

John Hodgkinson *In* Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations Feb. 1995 3 p (For primary document see N95-31061 11-03)

Copyright Avail: CASI HC A01/MF A02

The main theme of this presentation, is that of relating the handling qualities issues, and specifically the PIO, to aircraft safety. It is essential that the programme managers recognize that PIO is safety critical in that it is loss of control, and that when it is encountered, it is as dangerous as a structural failure of the airframe. The time delay which arises due to rate limiting in a control system has been identified as a contributing factor to the occurrence of pilot induced oscillations (PIO's). Recent discussions concerning PIO prevention measures have proposed the elimination of this time delay through an alternate control scheme. In response to this proposal, the SCARLET (Saturated Command And Rate Limited Elevator Time delay) project was initiated in order to study the effects of both the time delay and the elimination scheme on the handling qualities of a contemporary fly-by-wire aircraft. A flight experiment was carried out in 1992 using DLR's ATTAS In-Flight Simulator. The flight test included runs with two different control laws: a conventional control scheme and the alternate control scheme (ACS). Results of the experiment demonstrated both the negative effect of rate saturation and the effectiveness of ACS to reduce the equivalent time delay and improve tracking performance. In order to further validate the concept of an alternate control scheme, the algorithms were adapted for use with a model-following control system. Pilot-in-the-loop simulations have shown improved performance through the use of ACS during rate saturated conditions. A second flight test will be performed this year in order to further evaluate the use of the alternate control scheme to eliminate the rate limit induced time delay and reduce the danger of PIO. The past experience in Sweden with PIO is reviewed, which had been so publicly witnessed with the second accident to the JAS-39 aircraft at the Stockholm Water Festival. Prior to commencing on the JAS-39 project, SAAB's experience of the PIO phenomenon had commenced with the J-35 aircraft. This aircraft had high stick sensitivity combined with a linear gearing of the stick to elevon. Following the PIO, the solution devised was to add a nonlinear gearing and improve the stability augmentation of the system. For the next aircraft project, the AJ-37 Viggen, significant work was performed on the handling qualities and resistance to PIO, based upon new information received during the 1960's from Ashkenas, McRuer, and A'Harrah. By 1963, Sweden had developed its own specification for flight control system design and for handling qualities. The latest versions of this AJ-37 aircraft have a digital flight control system. The AJ-37 Viggen has never experienced a problem with PIO in its service to date. The JAS-39 flight control system originated from demonstration work performed by SAAB on a FBW AJ-37 Viggen aircraft. This aircraft had been flown with instability levels of up to 4 percent chord at low Mach Number. This was the limit for this aircraft. Although this aircraft was reported to have experienced Level 2 or 3 handling, due to excessive time delays within the flight control system, it never experienced rate limiting or PIO. On this basis, it was deemed that there was sufficient knowledge and confidence to proceed with the JAS-39 aircraft project, and the JAS-39 specification was written around this experience, with a demanding handling qualities requirement. AEROELASTIC PILOT-IN-THE-LOOP OSCILLATIONS

W. J. Norton *In* Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations Feb. 1995 14 p (For primary document see N95-31061 11-03)

Copyright Avail: CASI HC A03/MF A02

Pilot-induced oscillation (PIO) is an unwanted and inadvertent closed-loop coupling between the pilot and one or more independent response variables of an aircraft. PIO typically results when the pilot attempts to perform a high gain tracking task using the usual cues of acceleration or attitude. Control system and aircraft characteristics within the bandwidth in which the pilot is active can contribute to a coupling between the pilot response and aircraft dynamics. The result is a neutrally damped or undamped out-of-control condition in which the pilot is often making intentional extreme and repetitive inputs in an effort to damp the motion but only serves to enhance it. Pilot-augmented oscillation (PAO) is an unintentional closed-loop coupling which does not involve a tracking task. Another aircraft variable which may lead to PIO or PAO is aeroelastic deformation of the vehicle structure. This elastic response can produce pilot cues or aircraft rigid body motion which can be enhanced when the pilot attempts to damp the oscillation and PIO results. Or, the elastic oscillations alone may lead to PAO. The potential for aeroelastic pilot-in-the-loop coupling is not widely recognized, and this can mean resources expended in ineffectual or nonoptimal solutions to the problem until the aeroelastic source is recognized. This paper will characterize the aeroelastic/pilot coupling phenomena without reproducing the fundamental research which has already been published on more general PIO. Examples of aeroelastic PIO and PAO will be provided to illustrate the various ways in which the phenomena can manifest itself, including recent experiences with the C-17A and the V-22. An examination of the potential for predicting this coupling will also be provided. Lastly, recommendations for flight test methodology to uncover and investigate aeroelastic pilot-in-the-loop coupling will be provided. Author

HANDLING QUALITIES ANALYSIS ON RATE LIMITING ELEMENTS IN FLIGHT CONTROL SYSTEMS **c08**

Dietrich Hanke *In* Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced Oscillations Feb. 1995 18 p (For primary document see N95-31061 11-03)

Copyright Avail: CASI HC A03/MF A02

Rate saturation conditions caused by rate limiting elements (RLE's) in flight control systems can contribute to severe pilot induced oscillation. In order to gain more theoretical insight in this problem the paper deals with the development of rate limiter describing functions in order to establish a theoretical basis for open and closed loop handling qualities analysis in the frequency domain. Although rate limitation produces nonlinear system behaviour it could be shown that rate limiter describing functions could be applied to existing methods used in handling qualities analysis of pilot/aircraft systems. A new handling quality parameter, the rate limiter onset frequency, is defined as a measure of input amplitude and frequency. Here the onset frequency in reference to the system bandwidth could be a suitable parameter in defining handling qualities boundaries for flight control systems with RLE's. The response in amplitude and phase is presented for different types of input signals such as triangle and sinusoidal oscillations. Rate limiter cascading is considered, too. Further, the suitability of various existing handling quality criteria are compared with the RLE results especially with respect to PIO. Finally, the improvements in system behavior by applying an alternate control scheme (ACS), as proposed by A'Harrah, will be discussed. Derived from text

CALSPAN EXPERIENCE OF PIO AND THE EFFECTS OF RATE LIMITING

Charles R. Chalk *In* Advisory Group for Aerospace Research and Development, Flight Vehicle Integration Panel Workshop on Pilot Induced

Oscillations Feb. 1995 12 p (For primary document see N95-31061 11-03)
Copyright Avail: CASI HC A03/MF A02

The experience of PIO within the Calspan Corporation is considerable, following a long standing interest in the subject. During this experience, the major concern that has been uncovered is that of the attitude towards the pilot following a PIO incident. There is still a tendency in many areas of aviation to consider a PIO as a failure of the pilot, whereas it must be properly regarded as a failure of the control system and its design process. Over a period of some years, the Calspan Corporation has undertaken a series of experiments with the NT-33A and Lear Jet aircraft to examine the effects of rate limiting compensating devices. The notes which follow summarize the presentation given on some of the aspects which have been investigated both analytically and experimentally in flight tests.

AVIATION CAPACITY ENHANCEMENT PLAN 1994
1 Oct. 1994 364 p Limited Reproducibility: Document partially illegible
(AD-A292758; DOT/FAA/ASC-94-1) Avail: CASI HC A16/MF A03

A comprehensive review of Federal Aviation Administration programs intended to improve the capacity of the National Air Transportation System. The Plan identifies the causes and extent of capacity and delay problems currently associated with air travel in the U.S. and outlines various planned and ongoing FAA projects with the potential to reduce the severity of the problems in the future. The major areas of discussion are: (1) Airport Development; (2) Airport Capacity; (3) Airspace Capacity; (4) New Instrument Approach Procedures; (5) Technology for Capacity Improvement; and (6) Marketplace Solutions. ENVIRONMENTAL SUPPORT OF NAVAL AVIATION Final Report
Sam Brand and Steven B. Dresksler Feb. 1995 64 p
(AD-A292873; NRL/MR/7543-94-7218) Avail: CASI HC A04/MF A01

A two-pronged approach to providing environmental support to Navy aviation is described. One approach focuses on flight safety and efficiency, and the other focuses on support to the tactical mission planner. Products are discussed in terms of requirements and the technical issues associated with the development or implementation of the products. This insight should be useful not only to the operational, tactical, and environmental communities, but to the R&D community as well. DTIC

PATIENT/AIRCRAFT FORECASTING FOR THE STRATEGIC AEROMEDICAL EVACUATION LIFT-BED PROCESS M.S. Thesis
Donald F. Kimminau Mar. 1995 90 p
(AD-A293902; AFIT/GOA/ENS/95M-04) Avail: CASI HC A05/MF A01

The goal of this research is to develop a tool for the Global Patient Movement Requirements Center (GPMRC) to efficiently forecast Aeromedical Evacuation (AE) aircraft and schedule patients in the lift-bed process. During a contingency, GPMRC is responsible for requesting required airlift, and providing lift-bed candidates to the Theater Patient Movement Requirements Center. The objective is to evacuate all waiting patients while minimizing the number of C-141 aircraft which must to be dedicated to the AE mission. In the solution process, a short-term forecast of patient movement requirements is input, including number of patients, bed and aircraft availability, and hub preferences. A mixed integer linear program is formulated, and solved. Upon reaching optimality or a user-specified node limit, the user analyzes the solution and determines if the search will be continued. At process completion, a solution file is produced which contains a feasible schedule which minimizes the number of dedicated C-141s required. The programs developed to assist the solution process were tested with 16 data sets. While optimal solutions are not guaranteed to be found for every case, the process quickly produces good, feasible solutions and provides timely, valuable information to GPMRC so it can request airlift and provide lift-bed candidates to appropriate agencies. ICING SIMULATION IN THE AEROPROPULSION SYSTEMS TEST FACILITY PROPULSION DEVELOPMENT TEST CELL C-2 Final Report, 13 - 23 May 1994
C. S. Bartlett Jan. 1995 49 p
(AD-A293039; AEDC-TR-94-12) Avail: CASI HC A03/MF A01

The AEDC Propulsion Development Test Cell C-2 has been modified to provide simulated altitude icing conditions. Spray droplet clouds with droplet mass median diameters simulating natural icing clouds are produced with calibrated water atomizing spray nozzles. The proper amount of liquid water ingested by an engine in flight through icing clouds is simulated by injection of the proper water content into the airstream that enters a test engine. The addition of the icing simulation spray system provides the opportunity to conduct simulated icing testing in the large engine test cell. The system is capable of providing icing testing of large engines, inlets, windshields, wings, and other full-scale test articles. The results of system activation testing have been summarized. The system can be used to initiate clouds and reach steady controlled spray operation within 10 sec. The system is capable of varying the liquid water content (LWC) over a five-to-one range within 10 sec. The simulation spray can be terminated within 5 sec. The uniformity of the distribution of the supercooled water at the test section has been determined. The transient response of the spray system and the ability to operate at extreme cold conditions for icing testing are improvements beyond previous AEDC icing simulation system capabilities. DTIC

EFFECTS OF CIVIL TILTROTOR SERVICE IN THE NORTHEAST CORRIDOR ON EN ROUTE AIRSPACE LOADS Final Report
William W. Trigeiro, Xavier P. Szebrat, and Stephanie B. Fraser Oct. 1994 70 p Prepared in cooperation with NYMA, Inc.
(Contract DTFA01-93-C-0001)
(AD-A293586; MTR-94W0000150; DOT/FAA/AOR-100/94/008) Avail: CASI HC A04/MF A01

This report documents an analysis of the effects of the introduction of civil tiltrotor (CTR) service on en route airspace loads. The analysis is intended as one in a set of analyses designed to provide information to senior decision makers and other interested parties on the potential effects of CTR service on National Airspace System performance. The analysis uses a demand scenario that addresses the introduction of CTR services into the Northeast Corridor of the United States using several simplifying assumptions. This report also includes an update on the previously published report 'Civil Tiltrotor Northeast Corridor Delay Analysis (Based on the Demand Scenario Described in Civil Tiltrotor and Applications Phase 2: The Commercial Passenger Market).' This document is based on briefing materials developed to report on the results of this analysis. These briefing materials have not been expanded to the full text more typical of technical reports. Instead, this document contains copies of the briefing slides and the associated briefing text. DTIC

ANNUAL REVIEW OF AIRCRAFT ACCIDENT DATA: US GENERAL AVIATION CALENDAR YEAR 1993
12 May 1995 84 p
(PB95-215828; NTSB/ARG-95/01) Avail: CASI HC A05/MF A01

This report presents a statistical compilation and review of general aviation accidents which occurred in 1993 in the United States, its territories and possessions and in international waters. The accidents reported are all those involving U.S. registered aircraft not conducting operations under 14 CFR 121, 14 CFR 127, or 14 CFR 135. This report is divided into five sections: All Accidents; Fatal Accidents; Serious Injury Accidents; Property Damage Accidents; and Midair Collision Accidents. Several tables present accident parameters for 1993 accidents only, and each section includes

tabulations which present comparative statistics for 1993 and for the nine-year period 1984-1992. Author

AIRCRAFT EVACUATIONS THROUGH TYPE-3 EXITS I: EFFECTS OF SEAT PLACEMENT AT THE EXIT Final Report
G. A. McLean, M. H. George, C. B. Chittum, and G. E. Funkhouser Jul. 1995 13 p
(DOT/FAA/AM-95/22) Avail: CASI HC A03/MF A01

Simulated emergency egress from Type 3 over-wing exits was studied to support regulatory action by the FAA. Passageway width and seat encroachment distance adjacent to the Type-3 exit were the major variables of interest. Two subject groups of differing mean ages were employed in a repeated-measures evaluation of different passageway widths leading to the exit in the CAMI aircraft cabin evacuation facility. Main effects of passageway width and seat encroachment distance on egress rates were determined using analysis of variance (ANOVA). Main effects were found for passageway width (p less than .001), seat encroachment distance (p less than .001), and subject group (p less than .001). The passageway width resulted from slowed egress at 6 and 10 inch wide passageway relative to 13, 15, and 20 inch passageways; seat encroachment effects were found for maximum seat encroachments but not midpoint and minimum encroachment distances. The subject group effects were found to result from a general increase in egress time for the older subject group. The placement of seat assemblies at the Type-3 exit has significant effects on passenger egress through the exit opening. Narrow passageways and/or large encroachments of the seat into the area of the exit opening delay egress significantly. Relative to the younger subjects, older subjects were found to have a general increase in egress times at all seat placement configurations that did not appear to worsen as the access route to the exit was made more restrictive. QUALITATIVE ENVIRONMENTAL NAVIGATION: THEORY AND PRACTICE Ph.D. Thesis
Il-Pyung Park 1994 173 p
Avail: Univ. Microfilms Order No. DA9421385

In this thesis we propose and investigate a new model for robot navigation in large unstructured environments. Current models which depend on metric information contain inherent mechanical and sensory uncertainties. Instead we supply the navigator with qualitative information. Our model consists of two parts, the map-maker and the navigator. Given a source and a goal, the map-maker derives a navigational path based on the topological relationships between landmarks. A navigational path is generated as a combination of 'parkway' and 'trajectory' paths, both of which are abstractions of the real world into topological data structures. Traversing within a parkway enables the navigator to follow visible landmarks. Traversing on a trajectory enables the navigator to move reliably into a homogeneous space, based on shapes formed by visible landmarks that are robust to positional and orientational errors. Reliability measures of parkway and trajectory traversals are defined by appropriate error models that account for the sensory errors of the navigator, the motor errors of the navigator, and the population of neighboring objects. Error detection and error recovery methods are also encoded into the generated path. The optimal path is further abstracted into a 'custom map,' which consists of a list of verbal directional instructions, the vocabulary of which is defined by our environmental description language. Based on the custom map generated by the map-maker, the navigating robot looks for events that are characterized by spatial properties of the environment. The map-maker and the navigator are implemented using two cameras, an IBM 7575 robot arm and PIPE (Pipelined Image Processing Engine). Various experiments show the effectiveness of navigation 'in the large' using the proposed methods. Dissert. Abstr.

RESULTS FROM TESTS OF THE HONEYWELL INTEGRATED FLIGHT MANAGEMENT UNIT
B. Jalving 8 Jan. 1995 48 p
(Proj. FFIE/633/131.1)
(PB95-211355) Avail: CASI HC A03/MF A01

The Norwegian Defense Research Establishment (NDRE) has tested Honeywell Military Avionics' Integrated Flight Management Unit (IFMU) as part of a program for investigating alternative technologies and vendors for the new antiship missile for the Royal Norwegian Navy. The HG1700 Inertial Measurement Unit (IMU) considered for use in the missile contains the same GG1308 ring laser gyros and Sundstrand RBA 500 accelerometers as the IFMU. Among the tests carried out were static navigation, gyro compassing, dynamic navigation, and impact of vibrations. It was observed that the performance was dependent upon the flight profile. Gyro biases, accelerometer biases, and random walk coefficients have been estimated. Additionally, the applicability of the IMU navigation data for seeker stabilization has been investigated. The HG1700 unit is suitable for the new antiship missile. NTIS

DEVELOPMENT OF ADVANCED APPROACH AND DEPARTURE PROCEDURES. FAILURE SCENARIOS
L. J. J. Erkelens and J. H. vanDronkelaar 15 Sep. 1994 18 p
(PB95-198123; NLR-TP-93348-U) Avail: CASI HC A03/MF A01

Under a joint contract awarded by the Federal Aviation Administration (FAA) and the Netherlands Department of Civil Aviation (RLD), a flight simulator program was carried out on National Aerospace Laboratory's (NLR's) Research Flight Simulator (RFS) with 19 airline crews to evaluate various test scenarios concerning curved approaches and departures. The test program was flown under full Microwave Landing System (MLS) guidance with a simulated Boeing 747-200 aircraft. The scenarios included procedures for both to New York Area (John F. Kennedy International and La Guardia Airports) and Amsterdam International Airport Schiphol. Four curved approaches and two MLS departures have been evaluated. Crew ability to detect insidious failures and to respond to them were investigated. Crew performance and perception data were also measured in case of a simulated failure of the flight management computer during execution of a curved approach. The workload during a one-engine inoperative flight was also evaluated. NTIS

A NASPAC-BASED ANALYSIS OF THE DELAY AND COST EFFECTS OF THE WESTERN-PACIFIC REGION PRELIMINARY RESECTORIZATION EFFORT OF 1993 Technical Note
Joseph M. Richie and Douglas Baart Nov. 1994 145 p
(AD-A288696; DOT/FAA/CT-TN94/49; FAA-AOR-100-94-012) Avail: CASI HC A07/MF A02

This report contains the findings and analysis of the effects of the Western-Pacific Region (AWP) Preliminary Resectorization Plan of 1993 on local (AWP airports) and system-wide traffic delays. The National Airspace System Performance Analysis Capability (NASPAC) was used to perform this task, and calculates the local and system-wide delays with and without the AWP Resectorization Plan. Cost of delay was derived using the Cost of Delay Module based on these delays, on passenger cost, and on airline and aircraft specific cost. The results indicate that the proposed

resectorization will reduce the operational delay in years 1995 and 2000 at most AWP airports and system-wide with the maximum benefit occurring in the year 2000. On the other hand, resectorization does not favor the passengers for the future years modeled. However, in year 2000, the increase in passenger delay is less than for year 1995. DTIC

AN EXPLORATORY SURVEY OF INFORMATION REQUIREMENTS FOR INSTRUMENT APPROACH CHARTS Final Report, Nov. 1990
R. J. Hansman, Jr. and Mark Mykityshyn Mar. 1995 126 p
(Contract DTRS57-88-C-0078)
(AD-A293882; DOTVNTSC-FAA-95/2) Avail: CASI HC A07/MF A02

This report documents a user centered survey and interview effort conducted to analyze the information content of current Instrument Approach Plates (IAP). In the pilot opinion survey of approach chart information requirements, respondents indicated their preferences for approach information and at what phase of the approach they preferred to see this information. Both precision and non-precision IAP formats were examined. In addition to the survey. focused interviews were conducted with pilots who represent the full spectrum of operational IAP user communities from major domestic air carriers to general aviation. INTEGRATED TERMINAL WEATHER SYSTEM (ITWS) DEMONSTRATION AND VALIDATION OPERATIONAL TEST AND EVALUATION
Diana L. Klingle-Wilson 13 Apr. 1995 81 p
(Contract DTFA01-91-Z-02036)
(AD-A293932; ATC-234) Avail: CASI HC A05/MF A01

During summer 1994, MIT Lincoln Laboratory conducted the Operational Test and Evaluation Demonstration and Validation (Dem Val) of the Federal Aviation Administration's Integrated Terminal Weather System (ITWS). The purpose of the demonstration was to obtain user feedback on products and to prove that the ITWS products and concept were sufficiently mature to proceed with procurement. Dem Val was conducted at the Memphis international Airport from 23 May through 22 July and at the Orlando International Airport form 11 July through 19 August. Products were delivered to users at the Memphis Airport Traffic Control Tower (ATCT) and TRACON (Terminal Radar Approach Control), at the Memphis Air Route Traffic Control Center (ARTCC), at the Orlando international ATCT and TRACON, and at the Jacksonville ARTCC. in addition, ITWS displays were available to the National Weather Service forecast offices at Memphis, TN, and Melbourne, FL; to Northwest Airlines in Minneapolis, MN; and to Delta Airlines in Orlando, FL. This report documents the technical performance of the product generation algorithms. Each algorithm is described briefly, including the product operational and display concepts. The techniques by which the technical performance is assessed and the results of the assessment are presented. The performance of the algorithms is measured against the Minimum Operational Performance Requirements (MOPR), which products must meet to be considered operationally useful by the ATC user community. DTIC

N95-31572# Federal Aviation Administration, Cambridge, MA.
GUIDELINES FOR THE DESIGN OF GPS AND LORAN RECEIVER CONTROLS AND DISPLAYS Final Report
M. S. Huntley, Jr. Mar. 1995 128 p
(AD-A293753; DOT-VNTSC-FAA-95-7; DOT/FAA/RD-95-7) Avail: CASI HC A07/MF A02

Long range navigation (Loran) and global positioning system (GPS) receivers are widely used in aviation. The Loran and GPS receivers are similar in size and function but derive their navigation signals from different sources. The design of the controls, displays, and computer logic is usually similar for the two types of receivers from a single manufacturer, but differs substantially among manufacturers. Some or all of the designs may provide a suboptimal human-computer interface, which may result in simple time delays or in serious risks if the pilot cannot use the system effectively and efficiently. The design variations also make it difficult to certify receivers for different applications. As a result, the Volpe National Transportation Systems Center has sponsored a program of research to address issues in Loran and GPS receiver design. This report first reviews the literature on user experiences with Loran and GPS receivers and other types of similar, automated equipment. Second, the report reviews the major human factors references, texts, and individual journal articles that are relevant to the regulatory requirements for the receivers. Finally, specific human factors principles and guidelines are proposed for the design and certification of GPS and Loran receiver controls, displays, and control-display integration. DTIC

ANALYSIS AND MODELING OF AN AIRPORT DEPARTURE PROCESS M.S. Thesis
Joseph E. Hebert Mar. 1995 137 p
(AD-A293782; AFIT/GOA/ENS/95M-02) Avail: CASI HC A07/MF A02

This study analyzes departure delays at a major airport using probability models to represent this nonhomogeneous process. The models developed in this study expand on the Markovian models presently used by employing the method of stages to represent some of the model processes. This technique improves the user's ability to achieve a close fit for the service time probability distribution while maintaining the advantages of the Markovian model. The three types of models developed and compared all assume a Markovian system entry process. The first model uses an exponential distribution to model the service process. The second uses an Erlang distribution. The third models employs a unique server absence process to explicitly represents the periods of time when the server is unavailable to service departing aircraft. All three models generate results which correlate well with the delays actually observed. However, the Erlang model is preferred. Its results have lower variability than the exponential service time model. In addition, it generates solutions much faster than a typical application of the absence model. This model should be useful for improving capacity estimation and take-off delay prediction. DTIC

N95-32022# Federal Aviation Administration, Cambridge, MA.
INTEGRATION OF AIR TRAFFIC DATABASES: A CASE STUDY Final Report, Oct. - Nov. 1994
Charles T. Phillips Mar. 1995 62 p
(AD-A293691; DOT-VNTSC-FAA-94-29; DOT/FAA/AOR-100/95-01) Avail: CASI HC A04/MF A01

This report describes a case study to show the benefits from maximum utilization of existing air traffic databases. The study demonstrates the utility of integrating available data through developing and demonstrating a methodology addressing the issue of airport performance. The study utilized data bases which addressed the factors of airport capacity and aircraft delay, and focused on the single airport of Philadelphia International. Since avoidable delays impose major costs to the nation's airlines, the study objective was to better understand the conditions under which delays occur and their causal factors. This will provide guidance for decisions on airport investments which are justified with well-defined benefits. The report presents quantitative measures of average delay, number of delayed flights, and total delay. As expected, there were more delayed flights and longer average delays under poor weather conditions than under better weather conditions. However, total delay under good weather conditions considerably outweighs the total delay experienced under poor weather conditions. The report also

demonstrates a quantitative relationship between average delay and the demand/capacity ratio at the airport. This should prove to be especially useful in the investment analyses of airport improvements. DTIC

CONTROLLER RESOURCE MANAGEMENT: WHAT CAN WE LEARN FROM AIRCREWS? Final Report
Charmine Haertel and Guenther F. Haertel (Colorado State Univ., Fort Collins, CO.) Jul. 1995 41 p
(Contract DTFA02-93-P-7913)
(DOT/FAA/AM-95/21) Avail: CASI HC A03/MF A01

This paper provides an overview of the scientific literature regarding Crew Resource Management (CRM). It reaponds to tasking from the Office of Air Traffic Program Management to conduct studies addressing the application of team training models such as CRM for air traffic operational and administrative tasks. The authors report that there is no single model for CRM per se. They formulate a model by integrating common dynamic elements found in many CRM programs. The literature reviewed points out that current CRM research: (a) is primarily focused on flight deck CRM; (b) is insufficient to establish the superiority of CRM training over other team training alternatives; (c) has not identified the critical components of CRM team training; and (d) is limited in part by weaknesses in assessment methods and outcome criteria. The authors identify alternative assessment methods and performance criteria currently being explored by behavioral scientists. Finally, the authors discuss potential CRM techniques for enhancing Air Traffic Control Specialists operational tasks. Author

FACT SHEET FOR CONGRESSIONAL COMMITTEES. AIR TRAFFIC CONTROL: STATUS OF FAA'S MODERNIZATION PROGRAM
15 Apr. 1994 80 p
(GAO/RCED-94-167FS; B-247729) Avail: CASI HC A05/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20877 HC

This fact sheet is the fifth annual review of the Federal Aviation Administration's (FAA) comprehensive effort to modernize the nation's air traffic control system by acquiring new equipment, such as radars, computers, and communications systems. The fact sheet provides information on the status of modernization, giving special emphasis to 12 of the largest projects: Advanced Automation System, Air Route Surveillance Radar-4, Airport Surface Detection Equipment-3, Airport Surveillance Radar-9, Automated Weather Observing System, Central Weather Processor, Flight Service Automation System, Microwave Landing System, Mode Select, Radar Microwave Link Replacement and Expansion, Terminal Doppler Weather Radar, and Voice Switching and Control System. Derived from text

N95-32199# General Accounting Office, Washington, DC. Resources, Community, and Economic Development Div.
REPORT TO THE CHAIRMAN, SUBCOMMITTEE ON TRANSPORTATION AND RELATED AGENCIES, COMMITTEE ON APPROPRIATIONS, HOUSE OF REPRESENTATIVES. AIR TRAFFIC CONTROL: STATUS OF FAA'S PLANS TO CLOSE AND CONTRACT OUT LOW-ACTIVITY TOWERS
12 Sep. 1994 27 p
(GAO/RCED-94-265; B-257854) Avail: CASI HC A03/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20877 HC

The objectives are (1) to determine the reasonableness of FAA's plans to close level 1 (low-activity) air traffic control towers and contract out the operations of other level 1 towers, (2) to assess the reasonableness of the potential savings that could result from such actions, (3) to identify the factors that could impede FAA's plans to close and contract out towers, and (4) to identify steps that FAA can take to enhance its strategy for reassigning controllers from closed or contracted out level 1 towers. Of the 151 level 1 towers, 36 do not meet FAA's benefit-cost criteria for continued operations. FAA is planning to permanently close 23 of these towers within the next 3 years, saving as much as $5 million annually. Of the remaining 127 towers, 32 are currently contracted out. FAA estimates that it could save as much as $120 million (in constant 1994 dollars) if it contracts out the operation of the remaining level 1 towers by fiscal year 1997. FAA will not realize immediate savings primarily because of the short-term costs to relocate controllers to other facilities. Several factors may affect FAA's efforts to close or contract out level 1 towers quickly. First, according to FAA program management officials, the agency is receiving mixed signals from the Congress regarding level 1 towers. Second, FAA cannot contract out towers until the Department of Labor completes its wage determinations for each tower location. The FAA does not have a strategy for reassigning controllers from towers to be closed or contracted out to higher level facilities after fiscal year 1994. Also, since a number of controllers at level 1 towers have not been able to perform required duties at other facilities, FAA could incur significant costs to relocate controllers a second time if they do not succeed at higher-level facilities. A GENERAL INVERSE DESIGN PROCEDURE FOR AERODYNAMIC BODIES Ph.D. Thesis
Michael Lawrence Papay 1994 103 p
Avail: Univ. Microfilms Order No. DA9425587

A general inverse design procedure has been developed to use optimization techniques and generic surface descriptions for the purpose of aerodynamic shape design. A variety of flow regimes are examined from 2D inviscid, subsonic cases to 3D turbulent, supersonic problems. Surface descriptions have been generalized through the use of B-splines to model a variety of curves and shapes with a minimum of parameters. The process uses a computational fluid dynamics program, GASP (the General Aerodynamic Simulation Program), and several iterative and optimization techniques to examine bodies of interest. A 2D inviscid, subsonic airfoil test case demonstrates the ability of the procedure to solve problems governed by elliptic equations. A 3D, viscous, compressible flow over a forebody/canopy model of a supersonic fighter and its comparison to test data establishes the ability of the method to solve practical problems of interest. Several other test cases are performed, including an axisymmetric power law body and a 3D elliptic cone. Unconstrained multiparameter optimizations have been quite successful in matching target pressure coefficients and reproducing target body shapes. Dissert. Abstr.

MOVING BASE SIMULATION OF AN INTEGRATED FLIGHT AND PROPULSION CONTROL SYSTEM FOR AN EJECTOR-AUGMENTOR STOVL AIRCRAFT IN HOVER
Walter McNeill, E., William W. Chung, and Michael W. Stortz Jun. 1995 31 p
(RTOP 505-68-32)
(NASA-TM-108867; A-950046; NAS 1.15:108867) Avail: CASI HC A03/MF A01

A piloted motion simulator evaluation, using the NASA Ames Vertical Motion Simulator, was conducted in support of a NASA Lewis Contractual study of the integration of flight and propulsion systems of a STOVL aircraft. Objectives of the study were to validate the Design Methods for Integrated Control Systems (DMICS) concept, to evaluate the handling qualities, and to assess control power usage. The E-7D ejector-augmentor STOVL fighter design served as the basis for the simulation. Handling-qualities ratings were obtained during precision hover and shipboard landing tasks. Handling-qualities ratings for these tasks ranged from satisfactory to adequate. Further improvement of the design process to fully validate the DMICS concept appears to be warranted. Author

A WIND TUNNEL INVESTIGATION OF THE EFFECTS OF MICRO-VORTEX GENERATORS AND GURNEY FLAPS ON THE HIGH-LIFT CHARACTERISTICS OF A BUSINESS JET WING M.S. Thesis

Michelle Therese Martuccio Aug. 1994 129 p
(NASA-TM-110626; NAS 1.15:110626) Avail: CASI HC A07/MF A02

A study of a full-scale, semi-span business jet wing has been conducted to investigate the potential of two types of high-lift devices for improving aircraft high-lift performance. The research effort involved low-speed wind-tunnel tests of micro-vortex generators and Gurney flaps applied to the flap system of the business jet wing and included force and moment measurements, surface pressure surveys and flow visualization on the wing and flap. Results showed that the micro-vortex generators tested had no beneficial effects on the longitudinal force characteristics in this particular application, while the Gurney flaps were an effective means of increasing lift. However, the Gurney flaps also caused an increase in drag in most circumstances. Author

VALIDATION OF THE HELICOPTER ROTOR CODE HERO
J. Bosschers 11 Oct. 1993 23 p
(PB95-198040; NLR-TP-93418-U) Avail: CASI HC A03/MF A01

Some improvements are shown for the helicopter rotor code HERO. The code is based on a blade element method using relative simple inflow models and is presently being improved with respect to aerodynamic modeling. Experimental results are used to validate the performance characteristics and the inflow modeling. Calculations with the unsteady aerodynamics model of Leishman & Beddoes are shown. A preliminary empirical formula is presented to take rotational effects into account. The formula is implemented in a semi-empirical dynamic stall program, and a dynamic stall loop showing the influence of rotation is presented. NTIS

A NOVEL INSTRUMENTATION SYSTEM FOR MEASUREMENT OF HELICOPTER ROTOR MOTIONS AND LOADS DATA, PHASE 1 Final Report, 10 Aug. 1994 - 10 Mar. 1995
Robert McKillip, Jr. Apr. 1995 61 p
(Contract N00600-94-C-3087)
(AD-A293309; CDI-95-03) Avail: CASI HC A04/MF A01

Results of a Phase-1 SBIR study directed at a novel instrumentation system for the measurement of helicopter rotor motion and loads are described. Background into the requirements and needs of the measurement system are provided, along with a summary of past activities in this area. Consideration is then given to a novel scheme that incorporates blade-mounted accelerometer sensors with a simplified signal processing scheme to extract both rotor motion measurements, and to a limited extent, blade loading information. Issues regarding sensitivity of the system to modeling errors, nonlinearities and sensor bias errors are examined through detailed simulation and analysis. Also, a demonstration of the system performance for reconstructing flapping motion measurements is provided using Froude-scaled model rotor test results. Finally, implementation issues are discussed, and a plan for continued work leading to prototype development for this system is outlined. DTIC

PROBABILISTIC RELIABILITY MODELING OF FATIGUE ON THE H-46 TIE BAR M.S. Thesis
John C. OConnor Sep. 1994 84 p
(AD-A289926) Avail: CASI HC A05/MF A01

The H-46 helicopter has experienced early in-service failures in its tie bar. The tie bar is a multi-component system that is a critical part of the linkage, which attaches the rotor blade to the rotating hub of the helicopter. This research developed methodology to predict the life of the tie bar under nominal operational flight loads. A probability model is indispensable because a revised design has yet to accumulate field data, and laboratory testing can never be sufficiently extensive for non-parametric reliability prediction. An algorithm was developed for three and four component systems that will generate the probability of system failure based on the probability of failure in its components. Finite element analysis was conducted on the tie bar to determine stress on each component for all possible damage configurations of the tie bar. A given set of flight loads was resolved into boundary conditions for the stress analysis. A methodology was developed to determine the probability of failure of each component using an idealized load history, based on the expected stress-life (S-N) relation of the component at the stress levels experienced by the component. The result is a prediction method that can fortify laboratory results to predict the probability of failure of a system given the system load history. This model will be verified using the early in-service failure statistics of the current design and can be used to assess revised designs. The model will provide a prediction of the failure distributions, (the bell-shaped distribution) as a fabrication of flight hours, or one, two, three, and four elements of failures within the leaves of the tie bar. UNMANNED AERIAL VEHICLES. 1994 MASTER PLAN
31 May 1994 132 p Original contains color illustrations
Avail: CASI HC A07/MF A02

This 1994 Unmanned Aerial Vehicle (UAV) Master Plan is the sixth submission to Congress, providing the acquisition and technology strategies, management, and program plans for nonlethal UAVs. The UAV Joint Project Office is the single Department of Defense organization charged with management responsibility for UAV's; the United States Navy was designated as the Executive Service for nonlethal UAV programs. This plan is comprised of the following sections: executive summary; management; supporting the user; programs; commonality and interoperability; technology; analysis and simulation; integrated logistics support (ILS), training, and human systems integration (HSI); test and evaluation; international programs; resources; needs rationale; UAV characteristics; dual use of UAV's; and points of contact. COMPUTATIONAL METHODS FOR CONTROL AND OPTIMAL DESIGN OF AEROSPACE SYSTEMS Final Technical Report, 1 Jan. 1992 - 31 Mar. 1994
J. A. Burns and E. M. Cliff 31 May 1994 16 p
(Contract F49620-92-J-0078)
(AD-A292861; ICAM-94-06-03) Avail: CASI HC A03/MF A01

This final technical report contains a summary of the research funded by AFOSR under Grant F49620-92J-0078, titled Computational Methods for Control and Optimal Design of Aerospace Systems, for the period 1 January 1992 to 31 March 1994. During this period, the investigators concentrated on five problems; optimal design of forebody simulators, control of highly maneuverable aircraft, control of fluid flows, modeling and identification of smart materials, and robust control of nonlinear conservation laws. A new sensitivity equation method was developed for shape optimization and flow tailoring. This method was transitioned into software at the Arnold Engineering Development Center and at Virginia Tech. A new mathematical model for aircraft agility was used to investigate feedback control laws for time optimal maneuvers. New vortex shedding patterns were discovered for unsteady flows about rotating cylinders. The work on smart materials produced new models and computational methods for the dynamics of shape memory alloys. In addition, robust control theory was applied to nonlinear conservation laws yielding a new approach to sensor location. The report contains a complete list of papers produced during this period. ARTIFICIAL INTELLIGENCE TECHNIQUES FOR FLIGHT TEST PLANNING, PHASE 1 Final Report
Richard H. Stottler 28 Mar. 1995 52 p Limited Reproducibility: Document partially illegible
(Contract N00600-94-C-2972)
(AD-A293962; FR001) Avail: CASI HC A04/MF A01

We found that several AI techniques would be applicable to the development of a system to aid flight test engineers. Flight test engineers reported that test plan and test report creation to be their most time-consuming activities and that they often made informal use of similar plans and reports. Based on the requirements of the flight test engineers, we developed the design for the Automated Flight Test Engineering System (AFTES). To prove its feasibility we implemented and demonstrated critical portions in three Phase 1 prototypes. AFTES is feasible and will benefit the Navy substantially when it is implemented. The three prototypes showed that the most critical aspects could be implemented. Furthermore, the very positive response we received from flight test engineers over both the AFTES designs and the Phase 1 prototypes indicates that AFTES will be utilized when its implemented. Finally, the fact that the productivity of flight

test engineers will markedly improve is based on the fact that AFTES was designed with precisely this purpose, along with improving the quality of the plans and reports produced. For example, the test plan produced in a a few minutes by the prototype can take some less-experienced flight test engineers several days to produce. DTIC

A CASE STUDY OF THE TEAMING CONCEPT IN THE PROCUREMENT OF THE V-22 AIRCRAFT M.S. Thesis
Richard D. Colvard Dec. 1994 68 p
(AD-A293770) Avail: CASI HC A04/MF A01

This thesis is a case study of the V-22 Osprey program. It examines dual-sourcing of major weapon systems which was the original acquisition strategy for the V-22. It examines the history of the V-22 program management. The chronology of the program is presented from the birth of the Joint Services Aircraft Program in 1981 through the engineering, manufacturing, and development phase in 1994. The focus of this thesis is to look at the relationship between the Joint Program Office, the parent companies of Bell Helicopter, Inc. and Boeing Helicopter, Inc., and the Government. The thesis also looks at other strategies that have been used in major weapon systems procurements such as the F/A-18 aircraft program which is being procured sole-source with the prime/subcontractor arrangement. This thesis concludes that the acquisition of the V-22 has not been efficient and that Bell and Boeing Aircraft Companies, operating under a teaming concept, have not presented a single face to the Government. DTIC

MODELING F/A-18 FLIGHT HOUR PROGRAM COSTS USING REGRESSION ANALYSIS M.S. Thesis
Larry E. Arkley Dec. 1994 123 p
(AD-A293771) Avail: CASI HC A06/MF A02

This thesis is an in depth analysis of cost variance in Naval Air Reserve units flying the McDonnell Douglas F/A-18. The purpose of the thesis is to identify, analyze, and quantify the effect of variances in the cost per flight hour of the Naval Air Reserve's Flying Hour Program. The study begins with a review of the planning, programming, and budgeting system which is used to justify and fund the Flying Hour Program. Then three different methods of determining Flying Hour Program requirements are described. The four components of cost per hour within the Flying Hour Program (fuel, organizational maintenance activity, intermediate maintenance activity, and aviation depot level repairables) are defined. Finally, using regression analysis techniques, these four components of F/A-18 cost data are analyzed on the basis of the intensity of aircraft utilization: flight hours. The analysis includes a regression model to provide budgeters at the headquarter or squadron level the means for predicting aircraft maintenance and fuel costs given a utilization rate. The thesis concludes with areas recommended for further research. DTIC

REPORT TO THE CHAIRMAN, LEGISLATION AND NATIONAL SECURITY SUBCOMMITTEE, COMMITTEE ON GOVERNMENT OPERATIONS, HOUSE OF REPRESENTATIVES. UNMANNED AERIAL VEHICLES: PERFORMANCE OF SHORT-RANGE SYSTEM STILL IN QUESTION
15 Dec. 1993 19 p
(GAO/NSIAD-94-65; B-229489) Avail: CASI HC A03/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20877 HC

The Department of Defense (DOD) is acquiring the Short-Range Unmanned Aerial Vehicle (UAV) at an estimated cost of $4.1 billion to meet the needs of the military services for reconnaissance, surveillance, target acquisition, and intelligence missions. The Short-Range UAV's performance capability as demonstrated in recent testing is evaluated. Although DOD considered the short-range system's preproduction test results to be sufficient to justify its low-rate production, the detailed test results showed deficiencies that could jeopardize the system's capability to meet military requirements. In addition, several important performance requirements were either not tested or were tested under unrealistic conditions. Thus, DOD has committed to acquiring an unproven and possibly deficient system. This condition occurred because DOD allowed the Short-Range UAV program to be driven by schedule requirements rather than by demonstrated accomplishments, as required by DOD's stated policy. CASI

IMPROVED ALTIMETER SETTINGS FOR A-10 AIRCRAFT
Timothy D. Oram Feb. 1995 23 p
(AD-A293142; AWS/FM-95/001) Avail: CASI HC A03/MF A01

This forecaster memo describes a process designed to improve the bombing accuracy of A-10 aircraft equipped with the Low Altitude Safety and Targeting Enhancement (LASTE) system by improving altimeter setting accuracy. After finding unacceptable altitude errors during tests of LASTE Version 3.3 the 57th Test Group (57 TG) at Nellis AFB asked the 57 055/05W to develop a method for improving A-10 bombing accuracy by developing improved altimeter setting forecasts. The 57 TG also contracted for General Electric to include software in LASTE Version 4 to correct for these altitude errors automatically. This memo describes a method for improving altimeter setting forecasts in support of LASTE Version 3.3. It also explains basic altimetry theory and tells how the theory relates to the A-10 bombing problem. Finally, the memo provides weather forecasting tips for supporting the new LASTE Version 4. DTIC

APPARENT SIZE PASSIVE RANGE METHOD Patent
Walter L. Harriman, inventor (to Navy) 13 Dec. 1994 8 p Filed 15 Jul. 1993
(AD-D017360; US-Patent-5,373,318; US-Patent-Appl-SN-094663; US-Patent-Class-348-117) Avail: US Patent and Trademark Office

A method and apparatus provides instantaneous passive range measurement onboard an aircraft for determining the range between the aircraft and a target. The target may either be stationary or a slower moving vehicle. Calculation of the desired range is achieved using the formula: Range = (S/S')V(Cos a)(Cos b) where S = apparent target size; S' = rate of change of apparent size; V = round velocity; a = azimuth angle from aircraft eading to target; and b = elevation angle from the aircraft heading to the target. The apparatus consists of an automatic video tracker, a video camera, and a servo controlled aiming platform. The video tracker provides target size data. Resolvers on the aiming platform are utilized to determine the azimuth and elevation angles from the aircraft axis to the target. The azimuth angle is added to the aircraft drift angle to determine the total azimuth angle from the aircraft heading to the target. The drift angle and ground velocity are obtained from the aircraft inertial system. DTIC

SYNTHETIC TERRAIN IMAGERY FOR HELMET-MOUNTED DISPLAY. VOLUME 3: SOFTWARE USER'S MANUAL Final Report, 1 Jun. 1992 - 1 Mar. 1995
Rand Whillock, Bill Corwin, and Jeff Groat 15 Nov. 1994 16 p
(Contract F33615-92-C-3601)
(AD-A293613; WL-TR-95-3027) Avail: CASI HC A03/MF A01

The purpose of this document is to describe how to use the STI software program (STI). The software samples data from a preprocessed database created from the U.S. Defense Mapping Agency's Digital Terrain Elevation Data (DTED) database and renders, in perspective view, the visual scene. An NTSC video signal drives a helmet-mounted display. The Synthetic Terrain Imagery for Helmet Mounted Display program was written to present digital terrain elevation data to pilots in several different formats on an HMD. The program can be run stand-alone, in which case it behaves like the 'flight' program that is provided by Silicon Graphics, or it can be integrated into a simulation environment which communicates over the ethernet. ANALYSIS OF HEADS-UP DISPLAY QUICKENING VERSUS HANDLING QUALITIES M.S. Thesis
Mar. 1995 133 p
(AD-A293797; AFIT/GAE/ENY/95M-01) Avail: CASI HC A07/MF A02

This study investigated an analytical means of selecting the quickening time constant for the standardized heads-up display flight path marker. The theoretically determined time constant allowed a faster, less resource intensive means of selecting the quickening time constant. The theoretically best time constant for pilot-aircraft handling qualities was equal to the airframe pitch attitude high frequency zero time constant, T(sub theta 2). Flight test indicated an empirical, more labor intensive method yielded better handling qualities, even though paper analysis indicated the theoretical method was better. The theoretically determined time constant gave slightly lower handling qualities, but was less costly to implement than the empirical method. DTIC

SYNTHETIC TERRAIN IMAGERY FOR HELMET-MOUNTED DISPLAY, VOLUME 1 Final Report, 1 Jun. 1992 - 1 Mar. 1995
Bill Corwin, Rand Whillock, and Jeff Groat 15 Nov. 1994 77 p
(Contract F33615-92-C-3601)
(AD-A293612; WL-TR-95-3025) Avail: CASI HC A05/MF A01

In order to aggressively maneuver an aircraft at low altitude, the pilot must be aware of his attitude as well as the elevation of the surrounding terrain. Low altitude tactical maneuvering is difficult during day operations but becomes nearly impossible at night without an effective night attack system. A system that generates a terrain image from onboard data without the use of sensors would be valuable day or night under all weather conditions. Having a terrain image produced on a Helmet-Mounted Display (HMD) will provide a terrain reference wherever the pilot is looking, thus allowing for more aggressive tactical maneuvering at night. Therefore, with the advent of HMD technology, along with the ability to store a digital terrain data base on tactical aircraft, this capability can be realized. The overall objective of this program is to enhance tactical operations by utilizing a digital terrain system data base to generate a Synthetic Terrain Image(STI) on an HMD. DTIC

Partnerships between government agencies are an intellectually attractive method of conducting scientific research; the goal is to establish mutually beneficial participant roles for technology exchange that ultimately pays-off in a stronger R&D program for each partner. Anticipated and current aerospace research budgetary pressures through the 90's provide additional impetus for Government research agencies to candidly assess their R&D for those simulation activities no longer unique enough to warrant 'going it alone,' or for those elements where partnerships or teams can offset development costs. This paper describes a specific inter-agency system simulation activity that leverages the development cost of mutually beneficial R&D. While the direct positive influence of partnerships on complex technology developments is our main thesis, we also address on-going teaming issues and hope to impart to the reader the immense indirect (sometimes immeasurable) benefits that meaningful interagency partnerships can produce. WAVE ROTOR-ENHANCED GAS TURBINE ENGINES
Gerard E. Welch (Army Research Lab., Cleveland, OH.), Jones M. Scott, and Daniel E. Paxson Jun. 1995 15 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul 1995; sponsored by AIAA, ASME, SAE, and ASEE
(RTOP 505-90-58)
(NASA-TM-106998; E-9777; NAS 1.15:106998; ARL-TR-806; AIAA Paper 95-2799) Avail: CASI HC A03/MF A01

The benefits of wave rotor-topping in small (400 to 600 hp-class) and intermediate (3000 to 4000 hp-class) turboshaft engines, and large (80,000 to 100,000 lb(sub f)-class) high bypass ratio turbofan engines are evaluated. Wave rotor performance levels are calculated using a one-dimensional design/analysis code. Baseline and wave rotor-enhanced engine performance levels are obtained from a cycle deck in which the wave rotor is represented as a burner with pressure gain. Wave rotor-toppings is shown to significantly enhance the specific fuel consumption and specific power of small and intermediate size turboshaft engines. The specific fuel consumption of the wave rotor-enhanced large turbofan engine can be reduced while operating at significantly reduced turbine inlet temperature. The wave rotor-enhanced engine is shown to behave off-design like a conventional engine. Discussion concerning the impact of the wave rotor/gas turbine engine integration identifies tenable technical challenges. Author

EFFECTS OF INITIAL CONDITIONS ON A SINGLE JET IN CROSSFLOW
D. S. Liscinsky (United Technologies Research Center, East Hartford, CT.), B. True (United Technologies Research Center, East Hartford, CT.), and J. D. Holdeman Jul. 1995 13 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul 1995; sponsored by AIAA, ASME, SAE, and ASEE Original contains color illustrations
(RTOP 537-02-21)
(NASA-TM-107002; E-9782; NAS 1.15:107002; AIAA Paper 95-2998)
Avail: CASI HC A03/MF A01; 4 functional color pages

An experimental investigation of the effects of jet inlet flow conditions has been conducted for the isothermal mixing of a single jet injected into a crossflow. Jet penetration and mixing was studied using planar Mie scattering to measure time-averaged jet mixture fraction distributions. The effects of 'passive' control methods such as jet 'tabs' and jet swirl are reported. Mixing effectiveness, determined using a spatial unmixedness parameter based on the variance of the mean jet concentration distributions, was compared to a baseline case of a round jet injected into a uniform crossflow. All results are compared at a jet-to-mainstream momentum-flux ratio of 8.5. In the near-field, the mixing rates are similar to, or less than, the baseline configuration using this measure of mixedness. None of the tested configurations appear to significantly augment mixing within a downstream distance of 3 diameters of an equivalent-area round orifice. Author

OBJECT-ORIENTED APPROACH FOR GAS TURBINE ENGINE SIMULATION
Brian P. Curlett and James L. Felder Jul. 1995 34 p
(RTOP 505-69-50)
(NASA-TM-106970; E-9731; NAS 1.15:106970) Avail: CASI HC A03/MF A01

An object-oriented gas turbine engine simulation program was developed. This program is a prototype for a more complete, commercial grade engine performance program now being proposed as part of the Numerical Propulsion System Simulator (NPSS). This report discusses architectural issues of this complex software system and the lessons learned from developing the prototype code. The prototype code is a fully functional, general purpose engine simulation program, however, only the component models necessary to model a transient compressor test rig have been written. The production system will be capable of steady state and transient modeling of almost any turbine engine configuration. Chief among the architectural considerations for this code was the framework in which the various software modules will interact. These modules include the equation solver, simulation code, data model, event handler, and user interface. Also documented in this report is the component based design of the simulation module and the inter-component communication paradigm. Object class hierarchies for some of the code modules are given. A NUMERICAL MODEL FOR DYNAMIC WAVE ROTOR ANALYSIS
D. E. Paxson Jul. 1995 13 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; sponsored by AIAA, ASME, SAE, and ASEE
(RTOP 505-62-50)
(NASA-TM-106997; E-9776; NAS 1.15:106997; AIAA Paper 95-2800)
Avail: CASI HC A03/MF A01

A numerical model has been developed which can predict the dynamic (and steady state) performance of a wave rotor, given the geometry and time dependent boundary conditions. The one-dimensional, perfect gas, CFD based code tracks the gasdynamics in each of the wave rotor passages as they rotate past the various ducts. The model can operate both on and off-design, allowing dynamic behavior to be studied throughout the operating range of the wave rotor. The model accounts for several major loss mechanisms including finite passage opening time, fluid friction, heat transfer to and from the passage walls, and leakage to and from the passage ends. In addition, it can calculate the amount of work transferred to and from the fluid when the flow in the ducts is not aligned with the passages such as occurs in off-design operation. Since it is one-dimensional, the model runs reasonably fast on a typical workstation. This paper will describe the model and present the results of some transient calculations for a conceptual four port wave rotor designed as a topping cycle for a small gas turbine engine. Author

PRELIMINARY ASSESSMENT OF COMBUSTION MODES FOR INTERNAL COMBUSTION WAVE ROTORS
M. Razi Nalim Jul. 1995 14 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; sponsored by AIAA, ASME, SAE, and ASEE
(RTOP 505-90-58)
(NASA-TM-107000; E-9779; NAS 1.15:107000; AIAA Paper 95-2801)
Avail: CASI HC A03/MF A01

Combustion within the channels of a wave rotor is examined as a means of obtaining pressure gain during heat addition in a gas turbine engine. Several modes of combustion are considered and the factors that determine the applicability of three modes are evaluated in detail; premixed autoignition/detonation, premixed deflagration, and non-premixed compression ignition. The last two will require strong turbulence for completion of combustion in a reasonable time in the wave rotor. The compression/autoignition modes will require inlet temperatures in excess

of 1500 R for reliable ignition with most hydrocarbon fuels; otherwise, a supplementary ignition method must be provided. Examples of combustion mode selection are presented for two core engine applications that had been previously designed with equivalent 4-port wave rotor topping cycles using external combustion. Avail: CASI HC A03/MF A01; 11 functional color pages

Three dimensional turbulent reacting CFD analyses were performed on transverse jets injected into annular and cylindrical (can) confined crossflows. The goal was to identify and assess mixing differences between annular and can geometries. The approach taken was to optimize both annular and can configurations by systematically varying orifice spacing until lowest emissions were achieved, and then compare the results. Numerical test conditions consisted of a jet-to-mainstream mass-flow ratio of 3.2 and a jet-to-mainstream momentum-flux ratio (J) of 30. The computational results showed that the optimized geometries had similar emission levels at the exit of the mixing section although the annular configuration did mix-out faster. For lowest emissions, the density correlation parameter (C = (S/H) square root of J) was 2.35 for the annular geometry and 3.5 for the can geometry. For the annular geometry, the constant was about twice the value seen for jet mixing at low mass-flow ratios (i.e., MR less than 0.5). For the can geometry, the constant was about 1 1/2 times the value seen for low mass-flow ratios. Author

EFFECT OF VELOCITY AND TEMPERATURE DISTRIBUTION AT THE HOLE EXIT ON FILM COOLING OF TURBINE BLADES

Vijay K. Garg (AYT Corp., Brook Park, OH.) and Raymond E. Gaugler Jun. 1995 14 p Presented at the 40th Gas Turbine and Aeroengine Congress and Exposition, Houston, TX, 5-8 Jun. 1995; sponsored by ASME

(RTOP 505-62-52)

(NASA-TM-106954; E-9704; NAS 1.15:106954) Avail: CASI HC A03/MF A01

An existing three-dimensional Navier-Stokes code, modified to include film cooling considerations, has been used to study the effect of coolant velocity and temperature distribution at the hole exit on the heat transfer coefficient on three-film-cooled turbine blades, namely, the C3X vane, the VKI rotor, and the ACE rotor. Results are also compared with the experimental data for all the blades. Moreover, Mayle's transition criterion, Forest's model for augmentation of leading edge heat transfer due to freestream turbulence, and Crawford's model for augmentation of eddy viscosity due to film cooling are used. Use of Mayle's and Forest's models is relevant only for the ACE rotor due to the absence of showerhead cooling on this rotor. It is found that, in some cases, the effect of distribution of coolant velocity and temperature at the hole exit can be as much as 60% on the heat transfer coefficient at the blade suction surface, and 50% at the pressure surface. Also, different effects are observed on the pressure and suction surface depending upon the blade as well as upon the hole shape, conical or cylindrical. Author

METHOD FOR EXTRACTING FORWARD ACOUSTIC WAVE COMPONENTS FROM ROTATING MICROPHONE MEASUREMENTS IN THE INLETS OF TURBOFAN ENGINES Final Contractor Report

D. E. Cicon and T. G. Sofrin (Sofrin, T. G., Newington, CT.) May 1995 55 p

(Contract NAS3-26618; RTOP 538-03-11)

(NASA-CR-195457; E-9577; NAS 1.26:195457) Avail: CASI HC A04/MF A01

This report describes a procedure for enhancing the use of the basic rotating microphone system so as to determine the forward propagating mode components of the acoustic field in the inlet duct at the microphone plane in order to predict more accurate far-field radiation patterns. In addition, a modification was developed to obtain, from the same microphone readings, the forward acoustic modes generated at the fan face, which is generally some distance downstream of the microphone plane. Both these procedures employ computer-simulated calibrations of sound propagation in the inlet duct, based upon the current radiation code. These enhancement procedures were applied to previously obtained rotating microphone data for the 17-inch ADP fan. The forward mode components at the microphone plane were obtained and were used to compute corresponding far-field directivities. The second main task of the program involved finding the forward wave modes generated at the fan face in terms of the same total radial mode structure measured at the microphone plane. To obtain satisfactory results with the ADP geometry it was necessary to limit consideration to the propagating modes. Sensitivity studies were also conducted to establish guidelines for use in other fan configurations. Author

Avail: CASI HC A03/MF A01; 10 functional color pages

This paper addresses the mixing of air jets into the hot, fuel-rich products of a gas turbine primary zone. The mixing, as a result, occurs in a reacting environment with chemical conversion and substantial heat release. The geometry is a crossflow confined in a cylindrical duct with side-wall injection of jets issuing from round orifices. A specially designed reactor, operating on propane, presents a uniform mixture without swirl to mixing modules consisting of 8, 9, 10, and 12 holes at a momentum-flux ratio of 57 and a jet-to-mainstream mass-flow ratio of 2.5. Concentrations of O2, CO2, CO, and HC are obtained upstream, downstream, and within the orifice plane. O2 profiles indicate jet penetration while CO2, CO, and HC profiles depict the extent of reaction. Jet penetration is observed to be a function of the number of orifices and is found to affect the mixing in the reacting system. The results demonstrate that one module (the 12-hole) produces near-optimal penetration defined here as a jet penetration closest to the module half-radius, and hence the best uniform mixture at a plane one duct radius from the orifice leading edge. PARAMETRICS ON 2D NAVIER-STOKES ANALYSIS OF A MACH 2.68 BIFURCATED RECTANGULAR MIXED-COMPRESSION INLET

M. Mizukami and J. D. Saunders Jul. 1995 16 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; Sponsored by AIAA, ASME, SAE and ASEE

(RTOP 537-02-22)

(NASA-TM-107003; E-9784; NAS 1.15:107003) Avail: CASI HC A03/MF A01

The supersonic diffuser of a Mach 2.68 bifurcated, rectangular, mixed-compression inlet was analyzed using a two-dimensional (2D) Navier-Stokes flow solver. Parametric studies were performed on turbulence models, computational grids and bleed models. The computer flowfield was substantially different from the original inviscid design, due to interactions of shocks, boundary layers, and bleed. Good agreement with experimental data was obtained in many aspects. Many of the discrepancies were thought to originate primarily from 3D effects. Therefore, a balance should be struck between expending resources on a high fidelity 2D simulation, and the inherent limitations of 2D analysis. The solutions were fairly insensitive to turbulence models, grids and bleed models. Overall, the k-e turbulence model, and the bleed models based on unchoked bleed hole discharge coefficients or uniform velocity are recommended. The 2D Navier-Stokes methods appear to be a useful tool for the design and

analysis of supersonic inlets, by providing a higher fidelity simulation of the inlet flowfield than inviscid methods, in a reasonable turnaround time.

(AF Proj. 3037)
(AD-A293277; AL/OE-TR-1994-0130) Avail: CASI HC A04/MF A01

In the framework of the U.S. Air Force's Advanced Technology Active Noise Reduction Initiative - an experimental program was carried out to demonstrate the feasibility of a new concept of an Active Liner. Using a 1:4 scale model of a jet engine test cell augmenter 8 dB to 15 dB reduction of the low frequency (8 Hz to 80 Hz at full scale) was obtained by inserting one or two active liner segments into a typical lined augmenter. The topics covered in this report include: (1) problems caused by low frequency noise and their land use implications, (2) description of the active liner concept, (3) control strategies employed, (4) description of the model-scale augmenter including passive and active sections and the feedback control system, (5) experimental results, (6) full-scale ramifications and (7) risk assessment of full-scale implementation. FLIGHT ASSESSMENT OF THE ONBOARD PROPULSION SYSTEM MODEL FOR THE PERFORMANCE SEEKING CONTROL ALGORITHM ON AN F-15 AIRCRAFT
John S. Orme and Gerard S. Schkolnik Washington Jul. 1995 20 p
Presented at 31st AIAA/ASME/SAE/ASEE Joint Propulsion Conference, San Diego, CA, 10-12 Jul. 1995
(RTOP 533-02-03)
(NASA-TM-4705; H-2060; NAS 1.15:4705; AIAA Paper 95-2361) Avail: CASI HC A03/MF A01

Performance Seeking Control (PSC), an onboard, adaptive, real-time optimization algorithm, relies upon an onboard propulsion system model. Flight results illustrated propulsion system performance improvements as calculated by the model. These improvements were subject to uncertainty arising from modeling error. Thus to quantify uncertainty in the PSC performance improvements, modeling accuracy must be assessed. A flight test approach to verify PSC-predicted increases in thrust (FNP) and absolute levels of fan stall margin is developed and applied to flight test data. Application of the excess thrust technique shows that increases of FNP agree to within 3 percent of full-scale measurements for most conditions. Accuracy to these levels is significant because uncertainty bands may now be applied to the performance improvements provided by PSC. Assessment of PSC fan stall margin modeling accuracy was completed with analysis of in-flight stall tests. Results indicate that the model overestimates the stall margin by between 5 to 10 percent. Because PSC achieves performance gains by using available stall margin, this overestimation may represent performance improvements to be recovered with increased modeling accuracy. Assessment of thrust and stall margin modeling accuracy provides a critical piece for a comprehensive understanding of PSC's capabilities and limitations. Author

(NASA-TP-3527; E-9390; NAS 1.60:3527; ARL-TR-333) Avail: CASI HC A13/MF A03

A laser anemometer system was used to provide detailed surveys of the three-dimensional velocity field within the NASA low-speed centrifugal impeller operating with a vaneless diffuser. Both laser anemometer and aerodynamic performance data were acquired at the design flow rate and at a lower flow rate. Floor path coordinates, detailed blade geometry, and pneumatic probe survey results are presented in tabular form. The laser anemometer data are presented in the form of pitchwise distributions of axial, radial, and relative tangential velocity on blade-to-blade stream surfaces at 5-percent-of-span increments, starting at 95-percent-of-span from the hub. The laser anemometer data are also presented as contour and wire-frame plots of throughflow velocity and vector plots of secondary velocities at all measurement stations through the impeller. Author

NEW ADAPTIVE METHODS FOR RECONFIGURABLE FLIGHT CONTROL SYSTEMS, APPENDIX 1 Final Report, 1 Jul. 1992 - 31 Dec. 1994
Marc Bodson 15 Feb. 1995 116 p
(Contract F49620-92-J-0386)
(AD-A292711; AFOSR-95-0174TR) Avail: CASI HC A06/MF A02

The report discusses methods for the design of reconfigurable flight control systems. Model reference adaptive control algorithms were developed which allow for the rapid identification of aircraft parameters after failures or damages and for automatic control redesign. These algorithms are simple enough that they can be implemented in real-time with existing computers. Simulation results were obtained using a detailed nonlinear model of a fighter aircraft. The results demonstrate the ability of the adaptive algorithms to automatically readjust trim values after failures, to restore tracking of the pilot commands despite the loss of actuator effectiveness, and to coordinate the use of the remaining surfaces in order to maintain the decoupling between the rotational axes. The report also discusses analytical results that were obtained during the course of the research regarding the stability and convergence properties of multivariable adaptive control algorithms, the use of averaging methods for the analysis of transient response and robustness, and the estimation of uncertainty in dynamic models. A modified recursive least-squares algorithm with forgetting factor is also described which gives fast adaptation under normal conditions while keeping the sensitivity to noise limited when signal to noise ratios are poor. VORTICITY DYNAMICS AND CONTROL OF DYNAMIC STALL Final Report, 15 Apr. 1992 - 14 Jun. 1994
Patrick H. Reisenthel 18 Aug. 1994 129 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DAAL03-92-C-0013)
(AD-A288658; NEAR-TR-482; ARO-29049.4-EG-S) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The goal of the research was to understand key issues of vorticity dynamics prior to, during, and after the initiation of dynamic stall. The first portion of this work examined the indicial theory to the prediction of dynamic applicability stall. The research focused on extending the semi-analytical formalism of indicial theory to predict the vorticity fluxes and the vorticity

accumulation at the leading edge during unsteady maneuver. In the second portion of this work, highly accurate two-dimensional solutions of the Navier-Stokes equation were used on a model problem to investigate the Reynolds number scaling of incipient flow separation between Re = 50,000 and Re = 800,000. This portion of the work was motivated by the suggestion that the appearance of eruptive plumes of vorticity at high Reynolds number might be critical to the formation of the dynamic stall vortex. The results of the research appear to contradict the hypothesis that a form of Reynolds number bifurcation must take place at some intermediate laminar Reynolds number. Instead, self-similar behavior was observed, at least up to the time of formation of the primary stall vortex. Author

FLIGHT TEST VALIDATION OF A FREQUENCY-BASED SYSTEM IDENTIFICATION METHOD ON AN F-15 AIRCRAFT

Gerard S. Schkolnik, John S. Orme, and Mark A. Hreha (McDonnell-Douglas Aerospace, Saint Louis, MO.) Washington Jul. 1995 18 p Presented at the 31st AIAA/ASME/SAE/ASEE Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995

(RTOP 505-68-00)

(NASA-TM-4704; H-2059; NAS 1.15:4704; AIAA Paper 95-2362) Avail: CASI HC A03/MF A01

A frequency-based performance identification approach was evaluated using flight data from the NASA F-15 Highly Integrated Digital Electronic Control aircraft. The approach used frequency separation to identify the effectiveness of multiple controls simultaneously as an alternative to independent control identification methods. Fourier transformations converted measured control and response data into frequency domain representations. Performance gradients were formed using multiterm frequency matching of control and response frequency domain models. An objective function was generated using these performance gradients. This function was formally optimized to produce a coordinated control trim set. This algorithm was applied to longitudinal acceleration and evaluated using two control effectors: nozzle throat area and inlet first ramp. Three criteria were investigated to validate the approach: simultaneous gradient identification, gradient frequency dependency, and repeatability. This report describes the flight test results. These data demonstrate that the approach can accurately identify performance gradients during simultaneous control excitation independent of excitation frequency. Author

ACTIVE CONTROL TECHNOLOGY: APPLICATIONS AND LESSONS LEARNED [LES TECHNOLOGIES DU SYSTEME DE CONTROLE ACTIF: APPLICATIONS ET ENSEIGNEMENTS]

Jan. 1995 400 p In ENGLISH and FRENCH Presented at the Flight Mechanics Panel Symposium, Turin, France, 9-13 May 1994

(AGARD-CP-560; ISBN-92-836-0007-X) Copyright Avail: CASI HC A17/MF A04

In the last decade, Active Control Technology (ACT) has emerged from the realm of theory and modest experimental applications to full-scale use on production aircraft, while more elaborate forms of ACT are under test for the future production of aircraft. New technologies have been applied in military fighters to maximize maneuverability and agility, and in civil transports to reduce trim drag, lower pilot workload and improve riding qualities. During this symposium the status of Active Control Technology was assessed in light of the experience gained over the last decade. The symposium was organized around four sessions comprising 28 technical papers in all. These sessions focused on: Specifications for flight control design, Design and analysis methods, System integration and Implementation of experience. For individual titles, see N95-31990 through N95-32017.

THE ROLE OF HANDLING QUALITIES SPECIFICATIONS IN FLIGHT CONTROL SYSTEM DESIGN

Roger H. Hoh and David G. Mitchell *In* AGARD, Active Control Technology: Applications and Lessons Learned Jan. 1995 12 p (For primary document see N95-31989 11-08)

Copyright Avail: CASI HC A03/MF A04

The handling qualities specification should be an essential element of the flight control system design and testing for an active control technology (ACT) aircraft. This is a significant departure from previous conventional aircraft where handling qualities depended more on the configuration (tail size, control surface sizing, etc.). The necessity for incorporating the handling qualities specification into the flight control system design process has not been recognized by the industry, as evidenced by the fact that most of the ACT aircraft do not meet the requirements of the current handling qualities specification. This has resulted in excessive phase lag in the flight controls, and numerous cases of pilot induced oscillation. This paper reviews key handling qualities criteria for ACT aircraft as well as lessons that should be incorporated into specification upgrades and flight control design efforts. Author

THE PREVENTION OF PIO BY DESIGN

J. C. Gibson *In* AGARD, Active Control Technology: Applications and Lessons Learned Jan. 1995 12 p (For primary document see N95-31989 11-08)

Copyright Avail: CASI HC A03/MF A04

Control problems caused by poor pilot-aircraft closed loop characteristics have existed for as long as aircraft have been flown. The majority of them have been the result of excessive response amplitudes and phase lags conflicting with simple stability margin requirements. Their solutions have been rather straightforward and often amount to the provision of K/S-like responses, or sufficiently similar, within the bandwidths of interest. Most high order Pilot Induced Oscillation (PIO) problems have-been introduced, not by more complex fly by wire control laws, but by unnecessary lags or sometimes by excessive gain placed between the pilot and the response. The pilot is forced to operate in a region of excessive phase lag and response gain, typically with the impression that the aircraft is not actually responding to the commands. The solutions address the provision of adequate stability margins in much the same way as in earlier problems. The high order PIO problem is identified in the open loop attitude behavior in the uniquely defined PIO frequency region, in which the response lags the stick by 180 degrees or more. It is not necessary to model the pilot, who is found to operate in a synchronous manner with the attitude oscillation. The dominant feature in this is the rate zero crossing which acts to trigger the reversals of the control input. The input itself may take the form of a sinusoid, a relay switching action, or a mixture of the two. A number of simple criteria can be applied to control law design which have been found to ensure the prevention of high order PIO. The existence of a PIO problem can be identified with great certainty before flight by specific test methods, which should be applied with rigor no matter how much confidence exists in the design methods. Finally, it is crucial for all concerned to understand that if the underlying problem is there, no matter how extreme the pilot inputs may have to be to excite it, then it can be expected to happen in flight. It will be impossible to prevent it by pilot briefings.

EXPERIENCES WITH ADS-33 HELICOPTER SPECIFICATION TESTING AND CONTRIBUTIONS TO REFINEMENT RESEARCH

C. J. Ockier and H.-J. Pausder *In* AGARD, Active Control Technology: Applications and Lessons Learned Jan. 1995 20 p (For primary document see N95-31989 11-08)

Copyright Avail: CASI HC A03/MF A04

The introduction of Active Control Technology in rotorcraft created the need for new handling qualities requirements. In response to this, a new helicopter handling qualities specification was developed under the leadership

of the U.S. Army and published as Aeronautical Design Standard 33 (ADS-33). Since its introduction, research has been conducted to expand the handling qualities database on which ADS-33 is based. This paper presents DLR contributions to this research. A standard BO 105 was used to evaluate the applicability and repeatability of the current ADS-33C criteria in forward flight. As a result of this study, some data gaps were recognized and the criteria that need further verification were identified. The in-flight simulator ATTHeS was used for an investigation of the effects of bandwidth and phase delay and pitch-roll coupling on helicopter handling qualities in a high gain slalom tracking task. Results are shown that indicate a need to more tightly constrain the phase delay for the roll axis than in the current ADS-33 requirements. For the pitch-roll coupling criterion it is shown that although the format of the current ADS-33 requirements is valid for control and rate coupling, it cannot be used for coupling types typical of actively controlled helicopters. A frequency domain criterion that offers more comprehensive coverage of all types of pitch-roll coupling is proposed. Author

The flight control system of the Lavi Multimission fighter is described. The control laws design philosophy is given along with the control laws development, the flying qualities requirements and the final structure of the pitch axis (DFCS). The simulation phase is covered along with special control laws features. The question 'how does the Lavi fly?' is addressed. Problems uncovered during flights, and solutions found, are detailed and the flying qualities data are given. Finally, the program status is explained. Author

This paper discusses an application of several robust control methodologies such as H(sub infinity) optimal control, micro-synthesis and gain scheduling via linear fractional transformations applied to a flight control system. To illustrate the approach, a design model for the short period approximation of the Cessna Citation 500 has been chosen, for which certain handling quality requirements have to be met over a large set of operating conditions. For all these methods, the design framework remains the same, only the system 'norm' changes to the object to be minimized. The paper shows how these methods work and illustrates the features of the new approach. Author

The characteristic of a fuzzy controller is to use a knowledge expressed in natural language in the forms of expert rules to calculate the value of the control starting from the numerical information from the sensors. The implementation of such a pilot requires the interpretation of the numerical field symbolically and reciprocally. This is carried out by the use of fuzzy assemblies. The associated theory allows starting from consideration of precise measurement, the whole of the stated expert rules, and choice of suitable operators to deduce a value from control. It results in a particular structure of the fuzzy controllers, whose main characteristics are the subject of the first part of the presentation. The implementation on the example of the longitudinal pilot control of an aircraft is then presented. Two approaches were adopted: the first uses the rules of manual piloting formulated in natural language by the 'experts' who are the pilots. The second uses the laws resulting from a conventional autopilot to build rules of piloting. The results are presented in the perspective from a comparison between the two types of controllers, conventional or fuzzy. Transl. by CASI

THE CONTROL SYSTEM DESIGN METHODOLOGY OF THE STOL AND MANEUVER TECHNOLOGY DEMONSTRATOR

David J. Moorhouse and Kevin D. Citurs (McDonnell-Douglas Aerospace, Saint Louis, MO.) *In* AGARD, Active Control Technology: Applications and Lessons Learned Jan. 1995 11 p (For primary document see N95-31989 11-08)

Copyright Avail: CASI HC A03/MF A04

This paper documents the development of a full-envelope Integrated Flight/Propulsion Control system. A combination of classical and multivariable design methodologies was used, including a unique inverse procedure to produce second-order equivalent systems meeting specified flying qualities requirements. The implementation was based on a rational choice between the two methodologies. It is suggested that a parallel design approach in the beginning will produce efficient convergence on a practical optimum design. Finally, all control law revisions should be done analytically and only evaluated by simulation. Regardless of the design technique used, the process begins by specifying detailed design guidelines selected to meet the intent of MIL-F-8785C. Once the designs were complete and analyzed based on the design guidelines, manned flight simulation was used only to validate and demonstrate the flying qualities achieved prior to flight test. Problems encountered during simulation or flight testing were addressed first by reviewing the original design guidelines and evaluating the success achieved in implementing them. Derived from text

CONTROL LAW DESIGN USING H-INFINITY AND MU-SYNTHESIS SHORT-PERIOD CONTROLLER FOR A TAIL-AIRPLANE

L. Mangiacasale *In* AGARD, Active Control Technology: Applications and Lessons Learned Jan. 1995 11 p (For primary document see N95-31989 11-08)

Copyright Avail: CASI HC A03/MF A04

The recently developed methods H-infinity and mu-Synthesis are used in the design of a control law for a tail controlled unstable airplane. The design procedure has been applied with success and seems to be very promising in order to solve control design problems in real applications. The (H-infinity) + mu controller, characterized by a very large order (namely 34th), has been successfully reduced to one having order 5th with a very low decay in the overall performance. The reduced-order controller meets all the servo technical specifications demanded to the full-order one. At present it is under test as part of a 6-DoF simulation program to verify its real robustness in face of structured and unstructured perturbations. Author

In-flight simulators will play an important and unique role in the development process of future helicopter systems and in generating credible handling qualities data which establish design guides for the integrated helicopter systems including sophisticated cockpit technologies and high authority control systems. The Institute for Flight Mechanics of DLR has developed the helicopter in-flight simulator ATTHeS (Advanced Technology Testing Helicopter System) which is based on a BO 105 helicopter. The testbed is equipped with a full authority nonredundant fly-by-wire control system for the main rotor and a fly-by-light system for the tail rotor. In the simulation mode the testbed requires a two-man crew, a simulation and a safety pilot. The onboard computer system consists of two computers to which are assigned the separated tasks, data collection and digital control system. With the implemented software structure the flexibility is achieved to change the control laws without any changes in the real time process. Before undergoing any flight test with a new or modified control system, a real-time hardware/software-in-the-loop ground-based simulation has to be successfully performed. For the purposes of in-flight simulation an explicit model following control system was developed and the model following performance was evaluated in flight. This control system is composed of a dynamic feedforward, based on an extended model of the host helicopter, and an optimized feedback control system. The capability and flexibility of ATTHeS has been demonstrated in different test programs which have been related to the use of the testbed for test pilot training, handling qualities research, helicopter simulation, and control law design and evaluation including automatic navigation and hover position hold. Two X-29A aircraft were flown at the NASA Dryden Flight Research Center over a period of eight years. The airplanes' unique features are the forward-swept wing, variable incidence close-coupled canard and highly relaxed longitudinal static stability (up to 35-percent negative static margin at subsonic conditions). This paper describes the primary flight control system and significant modifications made to this system, flight test techniques used during envelope expansion, and results for the low- and high-angle-of-attack programs. Throughout the paper, lessons learned will be discussed to illustrate the problems associated with the implementation of complex flight control systems. Author

Aircraft operations at low altitudes often are affected by strong gusts and turbulence producing additional aerodynamic forces and moments. This results in extra aircraft accelerations and therefore in an unpleasant impact on passenger comfort and pilot workload as well as in extra structural loads. Active Control Technology is able to suppress these effects partly. The knowledge about the potential for improvement, the parameters of influence and the performance requirements for such gust alleviation systems is still quite small. Since the mid-seventies Dornier and DLR (Institute of Flight Mechanics) have been working together on BMFT programs developing systems to improve the ride quality in gusty weather. The developed Open-Loop Gust Alleviation System OLGA was investigated through dynamic wind tunnel experiments and flight-tested onboard the experimental aircraft Do 128 TNT. This research was continued by DLR developing the Load Alleviation and Ride Smoothing System LARS using the modified VFW 614 aircraft ATTAS (Advanced Technologies Testing Aircraft System). The Deutsche Aerospace Dornier Luftfahrt GmbH has concentrated on simulation studies for their aircraft types Do 228 and Do 328. The presented paper provides a brief description of the advantages of overall gust management systems considering lift, drag and pitch control. The following topics will be presented in detail: (1) the basic flight mechanics of gust load alleviation; (2) the design of integrated gust management systems; (3) simulation and flight test results; and (4) lessons learned and general perspectives. Loss of directional stability in a post-stall flight environment has become a major design issue for future fighter aircraft. Numerous studies have addressed this issue, either from an aerodynamics perspective or through use of propulsive forces generated by vectoring exhaust nozzles. The X-29 aircraft, with its forward swept wing and other advanced technologies, suffers loss of directional power above 40 degrees angle of attack (AOA). An exploratory development program was undertaken on this configuration to regain the lost stability through use of a pneumatic system on the aircraft nose which influenced the external flow field, generating significant side forces useful for control. Wind tunnel test results were inserted into the X-29 flight simulator at NASA Dryden Flight Research Facility and the simulator was used to support a critical flight experiment of this technology. This experiment is the subject of this paper. Author

The use of unmanned air vehicles (UAV) in support of the Navy from small ships to fulfill tasks such as reconnaissance of large areas will succeed only if the user gains a high amount of confidence in the reliable operation of such a system, especially during the take off and landing phase. Take off from and landing on small landing pads on aviation facility ships in all-weather conditions prefer the application of VTOL-UAV's (Vertical Take Off and Landing) with a coaxial rotor system. Manual take off and landing procedures which have to be applied during operational service both at day time and at night under all-weather conditions and ship motions overtax the service personnel already at low sea states. This fact requires automatic take off and landing procedures. The German Ministry of Defence commissioned Dornier (DASA) in November 1990 with the development, test and demonstration of an automatic take off and landing system on the basis of the Gyrodyne QH-50 drone helicopter in order to prove the feasibilty of such a system in general. The essential ship and sea state dependent motions of the landing pad - roll, pitch and heave - were simulated with a ship deck simulator. The customer's requirement consisted of ten automatic take offs and landings of the UAV from a 4 by 4 meters landing pad. The test and demonstration phase was performed on the airfield of Friedrichshafen in the presence of experts from several NATO-Countries by the end of 1991. Derived from text

Implementation of ACT in aircraft is now almost routine, and often essential in realizing performance requirements. However, unless a proactive and thorough approach is taken to ensuring that the effects of the flexibility of the airframe structure and its interaction with the FCS (Flight Control System) are analyzed and accounted for, costly development delays and control system redesigns may ensue. This paper is intended to discuss the basis of the phenomenon referred to at BAe Warton as FCS-Structural Coupling, the evolution of the methodology evolved at Warton to ensure

freedom from its effects, and the development directions required to advance the state of art in this field. Author

The RAFALE program was conceived from the beginning to define, develop and produce a general-purpose aircraft meeting the future needs of the State - the Army, Air Force, and Navy. The Navy version is intended to equip the French naval air forces by the end of the decade. It will operate starting from the conventional propulsion Foch and the Charles De Gaulle nuclear aircraft carrier. Furnished with a numerical flight control system, the RAFALE M01 prototype is the first aircraft with delta canards to be catapulted from an aircraft carrier (April 1993). It is also the first naval aircraft to use the original method of catapult-assisted dihedral launching. The study of naval aircraft catapult launching combines the technical disciplines implicit in the design of fighter aircraft: aerodynamics, structure, flight control, and aircraft systems. In the framework of this conference, the discussion has particularly focused on flight dynamics. It covers: the specifications of the RAFALE naval launching; some related aspects at the aircraft catapult design: flight control system, improved performance systems (dihedral launch, high-energy recovery rate); the ground tests; and the tests at sea. ALENIA - Aeronautica has been involved in Digital Autopilot design for the AMX and EF 2000 programs. The AMX is a subsonic attack aircraft whose Flight Control System is based on Fly-by-wire technology, incorporating an Hybrid Analog and Digital Flight Control Computer for Control and Stability augmentation in pitch, roll and yaw axes, which guarantees the aircraft capability of full performance; in addition the Flight Control System has also a conventional mechanical back-up in the pitch and roll axes, which guarantees aircraft safe re-entry after failure of both hydraulic and both electrical circuits. The paper deals with the development history of the AMX autopilot through design to flight test. In particular the paper addresses the design to specification relationship, the system development and clearance process and the flight test results. The EF 2000 programme is an international development for an agile, highly unstable Fly-by-Wire Air Superiority fighter. Within the EF 2000 consortium ALENIA has the responsibility for Basic Autopilot design. This design, currently in the early stages of development, poses peculiar problems due to the interaction of Autopilot (external) feedback loops and the basic stabilization (inner) loops. The paper address these peculiar aspects in conjunction with the specific design methodologies applied. Author

The objectives of the Experimental Aircraft Programme were to demonstrate various technologies relevant to a future combat aircraft within the rigors imposed by having to achieve flight clearance and demonstration. Prime areas for demonstration, among others, were modern cockpit displays, avionics systems integration, advanced material construction, advanced aerodynamics and active flight control. Nearly all future combat aircraft will have an unstable basic airframe due to the advantages that are accrued: smaller, lighter, aerodynamically more efficient, etc. Necessary to such an aircraft is a full time active control system. This paper outlines the philosophy and method taken to design the flight control laws and relates their development through the life of the programme. The experience gained from the three phase, 259 flight test programme is summarized. The success of the flight programme has provided a wealth of experience from the operation of the aircraft. In particular, and most impressive to the pilots, was the carefree handling capability; this was considered remarkable. A further success was the complete absence of pilot induced oscillation (PIO) tendency throughout the whole of the flight programme. Author

'Vectored thrust Aircraft Advanced flight Control' (VAAC) is a UK project, sponsored by the Ministry of Defence and managed by the Defence Research Agency (DRA). The project is investigating, through ground-based simulation and flight test on the VAAC Harrier research aircraft, the low speed flight control, handling and cockpit display concepts applicable to an aircraft replacing the Harrier. As part of the project, British Aerospace

Defence Limited have designed a revolutionary two-inceptor pitch plane control law for assessment on the project aircraft. This Control Law has now been flight tested and further developed 'in-flight' by the DRA, culminating in a series of successful flight demonstrations to guest pilots. During the latter stages of flight testing the Control Law was modified to allow single-inceptor operation. Flight testing has shown that both the two- and single-inceptor control strategies result in a large reduction in pilot workload, when compared with the VAAC Harrier's three-inceptor arrangement, during the transition from wing-borne to jet-borne flight and hover. This paper describes the Control Law's evolution from initial concept through to the results obtained from flight testing. Author

X-31: A PROGRAM OVERVIEW AND FLIGHT TEST STATUS c05

H. Ross and U. Neuberger *In* AGARD, Active Control Technology: Applications and Lessons Learned Jan. 1995 7 p (For primary document see N95-31989 11-08)

Copyright Avail: CASI HC A02/MF A04

The objective of the X-31 program (the first international US/German experimental program) was to develop a new fighter that can execute tactical maneuvers up to an angle of attack (AOA) of 70 degrees (which is far beyond the stall AOA) without the pilot losing control of the aircraft (poststall capability, PST). This capability extends aircraft performance with respect to deceleration capability, turn rate and radius, and pointing capability for weapon firing considerably and results in a distinctive improvement of the tactical advantages in close-in combat. The prerequisite for these capabilities is the use of thrust vector control to boost or even replace the aerodynamic controls which lose their effectiveness at low speeds and in the poststall regime. The technical development of the PST capability requires the application of new technologies in the areas of aerodynamics (separated vortex flow), propulsion (inlet aerodynamics and jet deflection) and in particular, flight control (unstable configurations, digital flight control systems, integrated thrust vector control). Flight test results of the X-31 showed that the four important basic maneuvers (safe flight and maneuvering at 70 deg. AOA, 360 deg. rolls about the velocity at 70 deg. AOA, poststall maneuvers at high load factors, and the 180 deg. J (or Herbst) turn with extremely small turn radii and high turn rates) have been successfully demonstrated. In Nov./Dec. 1993 the flight envelope was extended into the supersonic and flights with a helmet mounted display (HMD) were conducted. This paper gives an overview of the X-31 program and the results of the test flights. CASI

Over the last two decades, flight control system requirements have been in a state of transition. Rotary wing missions have become more demanding, requiring vehicle management systems capable of conducting highly aggressive missions under night / adverse-weather conditions in severe electromagnetic environments. The digital, fly-by-wire / optics control system technologies developed at Boeing Defense and Space Group, Helicopters Division to meet these air vehicle requirements are overviewed. These technologies, which integrate digital multimode control laws and sidestick controllers within redundant-reconfigurable architectures, provide the rotorcraft capabilities required for the 21st century. The advances in flight control design, as developed during various technology demonstrator programs and applied in production of the V-22 Osprey tiltrotor and the RAH-66 Comanche scout / attack helicopter, are summarized. The objective of this paper is to describe a variety of examples of control system design and application on the NRC Bell 205 Airborne Simulator. For background, this paper will first examine the physical characteristics of the Bell 205 and the mathematical models which have been developed to describe them. The paper then reviews the classical control design techniques which have been used to develop high bandwidth rate and attitude response type systems on the aircraft, and describes the empirically determined fixes which have become standard elements of these types of systems. To complete the paper, two sections will deal with application of modern control theories; the first describes a limited effort to develop a translational rate command system using a six degree of freedom model of the Bell 205 and a publicly available software package, MATLAB/Simulink. The second modern control theory section deals with a more detailed study performed in collaboration with Carleton University and supported by DND/CRAD to devise modern control theory controllers for the Bell 205. All discussions of the paper are substantiated with actual in-flight validation data to clearly demonstrate design successes and failures. Author

FLYING QUALITIES OF CIVIL TRANSPORT AIRCRAFT WITH ELECTRICAL FLIGHT CONTROL [LES QUALITIES DE VOL DE AVIONS DE TRANSPORT: CIVIL A COMMANDES DE VOL ELECTRIQUES]

D. Chatrenet *In* AGARD, Active Control Technology: Applications and Lessons Learned Jan. 1995 5 p In FRENCH (For primary document see N95-31989 11-08)

Copyright Avail: CASI HC A01/MF A04

This conclusion to the the conference covers the flying qualities and flight control systems (FCS) of transport aircraft equipped with electrical flight control systems, as seen by Aerospatiale. A retrospective look at the related technological developments over the past 25 years precedes a comparison between the Airbus A340 and A320. The main points in the differences between the FCS in the A320 and the A340 are associated with the compensation effects of the more flexible structure of the A340, its design for long-range ('minimum drag'), and the inherent limitations in take-off performance. PILOT INDUCED OSCILLATION: A REPORT ON THE AGARD WORKSHOP ON PIO

K. McKay *In* AGARD, Active Control Technology: Applications and Lessons Learned Jan. 1995 10 p Workshop held on 13 May 1994 (For primary document see N95-31989 11-08)

Copyright Avail: CASI HC A02/MF A04

Instability of the pilot/airframe combination has been a problem from the beginning of manned flight. The rapid advances made in aviation following the Second World War greatly increased the incidence of PIO problems and led to a large amount of research and development work aimed at understanding and mitigating these difficulties. Criteria and requirements were developed which could be used in design to obtain satisfactory PIO qualities. Nevertheless, in spite of all this work, and even with the great flexibility in modern control technologies available to the designer, PIO problems still often occur with new aircraft; in fact it is the power and responsiveness of modern control systems which makes them susceptible to various 'non-linear' effects such as time delays, rate limits, actuator saturation, etc., leading to unexpected PIO difficulties. With current experience, it is clear that a universal solution of the PIO problem still evades the engineering community. The cost of these problems in programme delay and financial terms is significant. The gathering together of specialists to discuss this problem, from their various points of view, has led to positive gains in the state of knowledge regarding PIOs; it has provided a significant step toward their elimination and contributed to the avoidance of PIO associated programme costs and penalties. This paper provides an overview of the results from the Workshop. Fuller details are to be published by AGARD in the proceedings of the Conference and Workshop in the near future and in a separate Advisory Report. Author

VIBRATION REDUCTION IN HELICOPTER ROTORS USING AN ACTIVELY CONTROLLED PARTIAL SPAN TRAILING EDGE FLAP LOCATED ON THE BLADE Ph.D. Thesis
Thomas Alexander Millott 1993 519 p
Avail: Univ. Microfilms Order No. DA9420455

This dissertation describes the development of an aeroelastic analysis of a four-bladed hingeless helicopter rotor configuration incorporating an individually controlled aerodynamic surface located on each blade, and its application to the simulation of helicopter vibration reduction through individual blade control (IBC). The structural, inertial, and aerodynamic loads on an isolated rotor blade and control surface combination with fully coupled flap-lag-torsional dynamics are developed explicitly using a symbolic computing facility. Two blade models are used: the first is a simple offset-hinged spring restrained rigid blade model, and the second is a more realistic fully elastic blade model. The inertial loads on the blade are developed using D'Alembert's principle and quasi-steady aerodynamics, including the effects of a partial span trailing edge flap, is used to formulate the aerodynamic loads. Four blades are combined in a FORTRAN code to represent a four-bladed fixed hub hingeless rotor blade configuration. The rotor trim and blade response solutions are treated in a fully coupled manner using the harmonic balance technique. Various open-loop and closed-loop controllers based on global and local system models are implemented to reduce 4/rev vibratory hub loads using both an actively controlled aerodynamic surface on each blade as well as conventional IBC, in which the complete blade undergoes cyclic pitch change. The effectiveness of the two approaches for the simultaneous reduction of the 4/rev hub shears and hub moments is compared. It was found that both approaches are very effective in producing substantial vibration reduction. Comparisons of power requirements to implement the control were carried out and it was discovered that conventional IBC requires 5 to 25 times more power to achieve approximately the same degree of vibration reduction. The effect of blade torsional flexibility on the vibration reduction effectiveness of the actively controlled aerodynamic surface was also considered and it was found that this parameter has a very substantial influence. This study clearly demonstrates the feasibility of this novel concept for vibration reduction. Based on the results obtained, this is potentially one of the most effective means for vibration reduction. Furthermore it has the unique feature that it does not utilize the conventional swashplate of the helicopter and thus it has no effect on its airworthiness characteristics.

A NUMERICAL STUDY OF THE STARTING PROCESS IN A HYPERSONIC SHOCK TUNNEL Ph.D. Thesis
Jang-Yeon Lee 1993 217 p
Avail: Univ. Microfilms Order No. DA9425077

This dissertation represents the first time calculations have been made of the unsteady viscous simulation of the starting process in a hypersonic shock tunnel including the bifurcation phenomenon due to the interaction of the reflected shock with the boundary layer generated by the incident shock in the shock tube. In order to simulate the unsteady viscous flow in the NASA Ames 16-inch hypersonic shock tunnel, which consists of axisymmetric shapes (shock tube and nozzle), rectangular shape (test cabin), and octagonal shape (diffuser), a time-dependent ADI (alternating direction implicit) axisymmetric full Navier-Stokes code with a second order upwind TVD (total variation diminishing) scheme and a time-dependent three-dimensional thin layer Navier-Stokes code with an explicit MacCormack TVD scheme have been developed. As shown in the code validation study, these Navier-Stokes codes with the high resolution TVD algorithms give fair agreement with available experimental data and exact solutions. Numerical simulations of the starting process for the NASA Ames 16-inch hypersonic shock tunnel show that during the reflected shock interaction process at the end of the shock tube, the bifurcation phenomenon and the strong vortices become dominant features. The vortices due to the reflected shock interactions appear in the axisymmetric simulation but are not generated in the two-dimensional flow. For the nominal testing condition, the starting process in the NASA Ames shock tunnel takes 1700 microsec. The required total testing time consists of the time for the starting process, 1.7 m sec, and the time for the flow establishment over a model in the test cabin which strongly depends on the model shape and size and model mounting location. For a 10 deg-cone model, the minimum required testing time is estimated as at least 2.7 m sec for the steady state.

NASA LEWIS RESEARCH CENTER'S PREHEATED COMBUSTOR AND MATERIALS TEST FACILITY
Steve A. Nemets (NYMA, Inc., Brook Park, OH.), Robert C. Ehlers (NYMA, Inc., Brook Park, OH.), and Edith Parrott Jun. 1995 11 p
(Contract NAS3-27186; RTOP 505-62-84)
(NASA-TM-106676; E-9012; NAS 1.15:106676) Avail: CASI HC A03/MF A01

The Preheated Combustor and Materials Test Facility (PCMTF) in the Engine Research Building (ERB) at the NASA Lewis Research Center is one of two unique combustor facilities that provide a nonvitiated air supply to two test stands, where the air can be used for research combustor testing and high-temperature materials testing. Stand A is used as a research combustor stand, whereas stand B is used for cyclic and survivability tests of aerospace materials at high temperatures. Both stands can accommodate in-house and private industry research programs. The PCMTF is capable of providing up to 30 lb/s (pps) of nonvitiated, 450 psig combustion air at temperatures ranging from 850 to 1150 g F. A 5000 gal tank located outdoors adjacent to the test facility can provide jet fuel at a pressure of 900 psig and a flow rate of 11 gal/min (gpm). Gaseous hydrogen from a 70,000 cu ft (CF) tuber is also available as a fuel. Approximately 500 gpm of cooling water cools the research hardware and exhaust gases. Such cooling is necessary because the air stream reaches temperatures as high as 3000 deg F. The PCMTF provides industry and Government with a facility for studying the combustion process and for obtaining valuable test information on advanced materials. This report describes the facility's support systems and unique capabilities. Author

During a series of painting operations in a horizontal-flow paint spray booth at Travis AFB, CA, baseline concentrations of four classes of toxic airborne pollutants were measured at 24 locations across a plane immediately forward of the exhaust filters, in the exhaust duct, and inside and outside the respirator in the painter's breathing zone (BZ). The resulting data were analyzed and used to design a modified ventilation system that (1) separates a portion of the exhaust exiting the lower portion of the booth, which contains a concentration of toxic pollutants greater than the average at the exhaust plane (split-flow); and (2) provides an option to return the flow from the upper portion of the exhaust to the intake plenum for mixing with fresh air and recirculation through the booth (recirculation). After critical

review by cognizant Air Force offices, and an experimental demonstration showing that a flame ionization detector monitoring the air entering the booth is able to detect excursions above the equivalent exposure limit for the solvents in the paint, the exhaust duct was reconfigured for split-flow and recirculating ventilation. EVALUATION OF ALTERNATIVE PAVEMENT MARKING MATERIALS Final Report

Keith W. Bagot Jan. 1995 50 p

(AD-A292973; DOT/FAA/CT-94/119) Avail: CASI HC A03/MF A01

This study was undertaken to evaluate potential alternative marking materials for use on airport pavement marking systems. The materials were evaluated for conspicuity, durability, rubber buildup, color retention, friction, environmental acceptability, and cost benefits. In all, five materials (two water-borne, two epoxies, and one methacrylic resin) were evaluated at three test airports around the country for a period of one year. The three test airports, chosen for their different climatic conditions, were Atlantic City, Greater Pittsburgh, and Phoenix Sky Harbor International airports. Epoxies and resins were more durable than water-borne paints in areas subject to heavy snowfall and snowplow activity, particularly when applied to Portland cement concrete surfaces. The epoxies tested, however, did show signs of yellowing after extensive ultraviolet exposure. It was also determined that the addition of silica and/or glass beads improved the conspicuity of the markings, improved friction, and minimized rubber adherence. The cost-benefit analysis showed that more durable materials and the addition of silica and/or beads does increase the initial cost of marking the airport surfaces but could reduce the number of painting cycles on many portions of the airport from several times per year to once every several years. FLOW QUALITY IMPROVEMENTS IN THE NASA LEWIS RESEARCH CENTER 9- BY 15-FOOT LOW SPEED WIND TUNNEL Final Report

E. Allen Arrington and Jose C. Gonsalez Cleveland, OH NASA Jun. 1995 20 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; sponsored by AIAA, ASME, SAE, and ASEE

(Contract NAS3-27186; RTOP 505-62-82)

(NASA-CR-195439; E-9465; NAS 1.26:195439; AIAA Paper 95-2390)

Avail: CASI HC A03/MF A01

The NASA Lewis Research Center 9- by 15-Ft Low Speed Wind Tunnel (LSWT) was recently upgraded with the addition of several flow quality improvement devices: four 10-mesh turbulence reduction screens and a flow straightening honeycomb (3/8-in. cell, length to diameter ratio, L/D = 16) in the settling chamber upstream of the test section, and a diffuser extension fairing downstream of the test section. Test section flow quality was measured prior to and following the tunnel modifications. Comparison of the pre- (baseline) to post-tunnel modification flow quality data will provide a gage of the effectiveness of the flow quality devices. An instrumented rake was used to provide both calibration and flow-field survey data at several stations in the test section. The flow-field parameters measured included total and static pressure, total temperature, pitch and yaw components of flow angle, and turbulence; boundary layer total pressure surveys were also made. The data indicated very good flow quality in the test section at all survey stations in terms of total pressure, total temperature, Mach number and flow angularity distributions, and turbulence levels. The data compared with that collected before facility flow quality additions indicate improvement in the test section Mach number distribution, flow angle distribution, and turbulence levels as well as an increase in the usable test section width. The temperature distributions can be further improved by increasing the cooling water flow into the facility heat exchanger. Author

COMPUTER MODEL TO SIMULATE TESTING AT THE NATIONAL TRANSONIC FACILITY

Raymond E. Mineck, Lewis R. Owens, Jr., Richard A. Wahls, and Judith A. Hannon Aug. 1995 45 p Sponsored by NASA, Washington

(RTOP 505-59-10-31)

(NASA-TM-4664; L-17459; NAS 1.15:4664) Avail: CASI HC A03/MF A01

A computer model has been developed to simulate the processes involved in the operation of the National Transonic Facility (NTF), a large cryogenic wind tunnel at the Langley Research Center. The simulation was verified by comparing the simulated results with previously acquired data from three experimental wind tunnel test programs in the NTF. The comparisons suggest that the computer model simulates reasonably well the processes that determine the liquid nitrogen (LN2) consumption, electrical consumption, fan-on time, and the test time required to complete a test plan at the NTF. From these limited comparisons, it appears that the results from the simulation model are generally within about 10 percent of the actual NTF test results. The use of actual data acquisition times in the simulation produced better estimates of the LN2 usage, as expected. Additional comparisons are needed to refine the model constants. The model will typically produce optimistic results since the times and rates included in the model are typically the optimum values. Any deviation from the optimum values will lead to longer times or increased LN2 and electrical consumption for the proposed test plan. Computer code operating instructions and listings of sample input and output files have been included. Author

A RASCAL IN-BORE DYNAMIC ANALYSIS OF THE TASK B AND TASK C ELECTROMAGNETIC RAILGUNS Report, Aug. - Sep. 1994
Lawrence W. Burton Apr. 1995 88 p
(AD-A292742; ARL-TR-726) Avail: CASI HC A05/MF A01

Previous RASCAL in-bore gun dynamics analyses 90-mm railguns have shown high transverse accelerations can be expected because of anomalies in the bore straightness. A request was made for similar analyses to be made for the Task B and Task C 90-mm railguns, with the Sabot Launched Electromagnetic Gun KE (SLEKE) 2 projectile design. Results of the RASCAL analyses showed the importance of matching the contact stiffness of the rear and front bore riders of the SLEKE 2 designs. Numerous cases were run to slow the effects of variations in contact stiffness. Mismatched contact stiffness resulted in elevated transverse accelerations at the less stiff of the two bore riding contacts. Comparisons of the results of this work are made against previous RASCAL analyses. These results verify the effect a kink in the bore centerline profile has on the projectile's in-bore response. (NASA-CR-195471; E-9657; NAS 1.26:195471) Avail: CASI HC A05/MF A01

In designing a satellite system with on-board processing, the selection of a switching architecture is often critical. The on-board switching function can be implemented by circuit switching or packet switching. Destination-directed packet switching has several attractive features, such as self-routing without on-board switch reconfiguration, no switch control memory requirement, efficient bandwidth utilization for packet switched traffic, and accommodation of circuit switched traffic. Destination-directed packet switching, however, has two potential concerns: (1) contention and (2) congestion. And this report specifically deals with the first problem. It includes a description and analysis of various self-routing switch structures, the nature of contention problems, and contention and resolution techniques. Author

A FEEDBACK LINEARIZATION APPROACH TO ORBITAL MANEUVERS Ph.D. Thesis
Sanguk Lee 1994 110 p
Avail: Univ. Microfilms Order No. DA9420253

New methods for obtaining optimal orbital maneuvers of a space vehicle in total velocity change are described and applied. The elegance of Lambert's Theorem is combined with feedback linearization and linear optimal control to obtain solutions to nonlinear orbital maneuver problems. In particular, geocentric orbital maneuvers with finite-thrust acceleration are studied. The full nonlinear equations of motion are transformed exactly into a controllable linear set in Brunovsky canonical form by using feedback linearization and choosing the position vector as the fully observable output vector. These equations are used to pose a linear optimal tracking problem with a solution to the Lambert's impulsive-thrust two-point boundary-value problem as the reference orbit. The same procedure is used to force the space vehicle to follow a linear analytical solution to the continuous low-thrust orbital maneuver problem between neighboring orbits. Limits on thrust magnitudes are enforced by adjusting the weights on the states in the performance index, which is chosen to be the sum of integrals of the square sum of new control variables and the square sum of state variable errors from the reference trajectory. For comparison purpose, the feedback linearized equations are used to obtain a simple closed-form solution to an orbital maneuver problem without the use of a reference trajectory. In this case, the performance index was chosen as the integral of the square sum of new control variables only. Three different examples, coplanar rendezvous between neighboring orbits, large coplanar orbit transfer, and non-coplanar orbit transfer, are used to show the advantages of using the new methods introduced in this dissertation. The minimum-eccentricity orbit,

Hohmann transfer orbit, and minimum energy orbit were used in turn as the reference trajectories. The principal problems encountered in using the new methods are the choices of the proper reference trajectory, a suitable time-dependent scalar weighting function, and appropriate constant weighting matrices. CONTROL OF FLEXIBLE SPACECRAFT STRUCTURES USING H-INFINITY WAVE ABSORBING CONTROL M.S. Thesis
Ronald E. Strong Dec. 1994 68 p
(AD-A293141) Avail: CASI HC A04/MF A01

This work studies the use of a wave absorbing control law for vibration suppression of flexible spacecraft structures. A major advantage of this method is that it does not involve truncation into a finite dimensional mathematical model. A closed loop scattering matrix was derived which gives the relationship between incoming waves, outgoing waves, sensor and actuator. The control law was determined by minimizing the H-infinity norm of this matrix. The control law was applied to the Naval Postgraduate School's Flexible Spacecraft Simulator (FSS) for vibration suppression. The simulator's flexible beam was controlled using piezoceramic wafers as sensors and actuators. The H-infinity wave absorbing controller contributed significant damping to the structure, especially at the first mode of 1 Hz. Therefore, wave absorbing control and piezoceramic sensors and actuators offer a viable approach for vibration suppression of space structures. DTIC

ASSESSMENT OF THE NASA ORBITAL DEBRIS ENGINEERING MODEL Final Report, Apr. - Jun. 1992
K. W. Yates and F. M. Jonas Feb. 1995 89 p
(Contract F29601-89-C-0001)
(AD-A293350; PL-TR-92-1032) Avail: CASI HC A05/MF A01

This report presents an assessment of the orbital debris engineering model which predicts near and long term orbit debris environments on spacecraft in low earth orbit. The model predicts debris flux environment, mass, and collision velocity distributions. The empirically based model is a curve fit to measured data and incorporates results derived from the NASA EVOLVE code. The data base includes US Space Command orbital element sets, Aricebo and Goldstone radar observations, MIT/Lincoln Laboratory Experimental Test System and Ground based Electrooptical Deep Space Surveillance optical data, and surface impact data from the Solar Maximum Mission. The model is most sensitive to the small debris particles and becomes undefined as the particle size approaches zero. The model is least sensitive to changes in orbital altitude. The model predicts essentially constant flux greator than 1000 km and does not reproduce measured data at these altitudes. The uncertainty is shown to be a factor of 2-4 for an altitude of 500 + 200 km (all particle sizes) and for sizes greater than 10 cm (for all altitudes), and at least an order of magnitude for all other sizes and altitudes. The collision-velocity distribution, and particle mass expressions represent extremely gross approximations of the environment. On the basis of the results of the analysis, it is recommended the model's use be restricted to altitudes le ss than 1000 km, debris sizes from 10(exp -4) to 10(exp -3) cm, and for projections through the year 2010. A MANUAL FOR PYROTECHNIC DESIGN, DEVELOPMENT AND QUALIFICATION
Laurence J. Bement and Morry L. Schimmel (Schimmel Co., Saint Louis, MO.) Jun. 1995 82 p
(RTOP 297-50-00-02)
(NASA-TM-110172; NAS 1.15:110172) Avail: CASI HC A05/MF A01

Although pyrotechnic devices have been singularly responsible for the success of many of the critical mechanical functions in aerospace programs for over 30 years, ground and in-flight failures continue to occur. Subsequent investigations reveal that little or no quantitative information is available on measuring the effects on performance of system variables or on determining functional margins. Pyrotechnics are considered to be readily available and, therefore, can be managed by any subsystem in which they are applied, such as structure, propulsion, electric power, or life support. The primary purpose of this manual is to alter the concept that the use of pyrotechnics is an art and refute 'justifications' that applications do not need to be understood by providing information on pyrotechnic design, development, and qualification on an engineering basis. Included are approaches to demonstrate functional reliability with less than 10 units, how to manage pyrotechnic-unique requirements, and methods to assure that the system is properly assembled and will perform the required tasks. COMPUTER INTERFACE DEVELOPMENT FOR THE PETITE AMATEUR NAVY SATELLITE (PANSAT) SIMULATOR M.S. Thesis
Thomas C. Calvert Dec. 1994 145 p
(AD-A293263) Avail: CASI HC A07/MF A02

This thesis describes the development of personal computer interfaces for the Digital Control Subsystem (DCS) and Electrical Power System (EPS) of the Naval Postgraduate School's Petite Amateur Navy Satellite Simulator project. The work includes a brief description of related PANSAT and PANSAT simulator subsystems. The laboratory activity that provided the information for this work, namely, programming in the LabVIEW software programs G graphical programming language, involved the generation of programming code for controlling and reading data from the simulators component subsystems. Where appropriate, there is limited discussion of key satellite and simulator component designs and installations. Through the use of documentation and illustrative figures, the programming and display components of the interfaces are shown to be functional in the simulator environment. Instructions for making anticipated design accommodations are included. DTIC

SPACE SYSTEMS ENVIRONMENTAL INTERACTION STUDIES
M. A. Morgan, Alan C. Huber, John O. McGarity, David J. Sperry, and Scott J. Moran 30 Aug. 1994 31 p
(Contract F19628-91-C-0112)
(AD-A293826; PL-TR-94-2215; SR-3) Avail: CASI HC A03/MF A01

The preparation of Ground Support Equipment (GSE) hardware and software, as well as, attending to launch support concerns prior to and after APEX launch, constitutes the extent of the effort expended on Task 1 (the Photovoltaic Array Space Power Plus Diagnostics (PASP Plus) experiment). Previously written test software was refined and new code generated, in order to accommodate real-time instrument performance monitoring during ground contact periods, and to facilitate the display of historical instrument performance data after a downlink opportunity. Under Task 2, the Charging Hazards and Wake Studies (CHAWS) program, Amptek, Inc. acted largely in a consultative and support role to PL/GPSG during this report period. Under Task 3 (the Space Wave Interactions with Plasmas Experiment (SWIPE)) GSE hardware was completed, and software was written and tested, for the electronics module of the EPI instrument on the OEDIPUS-C program. Two flight boxes are now in-house, fully assembled. Flight software for the constituent elements within the instrument was completed, and instrument functionality was fully exercised and checked. No additional change is envisaged to either hardware or software at this time. DTIC

ON-ORBIT TRUSS STRUCTURE TELE-OPERATION EXPERIMENT BY ENGINEERING TEST SATELLITE-7

Isao Yamaguchi, Koutarou Matsumoto, and Takashi Kida Aug. 1994 21 p In JAPANESE

(ISSN 0389-4010)

(NAL-TR-1246) Avail: CASI HC A03/MF A01

This report describes a preliminary ground test using the laboratory model of a truss structure and small research manipulator system which is a scaled model of the on-orbit truss structure experiment on Engineering Test Satellite-7(ETS-7). ETS-7 will be launched into low earth orbit by the H-2 rocket in 1997. This experimental application satellite is now being developed to establish rendezvous and docking technologies and remote tele-robotics technologies. National Aerospace Laboratory will participate in on-orbit experiments of remote deployment and construction of truss structures by using an on-board manipulator system. Author

STRUCTURAL ANALYSES OF THE JPL MARS PATHFINDER IMPACT

Kenneth W. Gwinn 1994 7 p Presented at the 13th AIAA Aerodynamic Decelerator Systems Technology Conference, Clearwater Beach, FL, 15-19 May 1995

(Contract DE-AC04-94AL-85000)

(DE95-009581; SAND-94-2324C; CONF-950582-1) Avail: CASI HC A02/MF A01

The purpose of this paper is to demonstrate that finite element analysis can be used in the design process for high performance fabric structures. These structures exhibit extreme geometric nonlinearity; specifically, the contact and interaction of fabric surfaces with the large deformation which necessarily results from membrane structures introduces great complexity to analyses of this type. All of these features are demonstrated here in the analysis of the Jet Propulsion Laboratory (JPL) Mars Pathfinder impact onto Mars. This lander system uses airbags to envelope the lander experiment package, protecting it with large deformation upon contact. Results from the analysis show the stress in the fabric airbags, forces in the internal tendon support system, forces in the latches and hinges which allow the lander to deploy after impact, and deceleration of the lander components. All of these results provide the JPL engineers with design guidance for the success of this novel lander system. DOE

VIBRATION CONTROL OF SPACECRAFTS AND SPACE STRUCTURES FROM LIFT-OFF TO ON-ORBIT ENVIRONMENTS Ph.D. Thesis

Gina Jimo Lee-Glauser 1994 201 p

Avail: Univ. Microfilms Order No. DA9422826

Vibration suppression of spacecraft and large flexible space structures using passive and active vibration control mechanisms are studied. Part 1 of this thesis is concerned with developing effective passive vibration control systems for protection of payload during lift-off. Two new trunnion designs (linear rubber bearing and resilient friction) for protecting the space shuttle payload and its sensitive subsystem during lift-off are presented and their effectiveness is analyzed. The results are compared with those for pure friction (current method in use with a treated friction surface) trunnions and fixed base (rigidly attached) case. Deterministic excitations including sinusoidal and the Space Transportation System mission 41 lift-off acceleration are used as dynamic input of the orbiter. Effects of the trunnion friction and flexibility on vibrations of payload and its subsystem are evaluated. Sensitivity analyses related to the vibration control systems and the flexible payload parameters are also performed. In Part 2 of the thesis, the probabilistic performance analysis of various linear and nonlinear passive vibration control systems under random orbiter lift-off excitations is presented. A simple stochastic model for generating synthetic orbiter lift-off accelerations is developed. This method is based on a filtered Gaussian white noise model which accounts for the nonstationary time evolution of amplitude and frequency content of orbiter lift-off accelerations. The peak responses of the payload with various vibration control systems are evaluated. Statistically derived acceleration response spectra are compared with those for the actual flight data for a single degree-of-freedom payload model. System performance with and without the passive vibration control systems are analyzed, and the effectiveness of vibration isolation devices are discussed. Part 3 of the thesis is concerned with developing an optimal active vibration absorber for microgravity environment, as well as for protection of payload during shuttle lift-off. The developed active vibration absorber is a second-order dynamic system which can provide effective control of vibrations for large flexible space structures with collocated sensors/actuators while guaranteeing closed-loop stability. Two methods for optimizing the active vibration absorber parameters (minimum resonant amplitude and the frequency matched) were evaluated. Numerical and experimental results under sinusoidal and random excitations were used to evaluate the effectiveness of the active controller. Performances of the active and passive vibration control systems under orbiter lift-off environment are compared using a five degree-of-freedom lump parameter model of a satellite. The presented performance analyses of the deterministic and probabilistic results show that, with proper design, the passive vibration control systems significantly reduce the peak acceleration and displacement experienced by the payload and its subsystem at high to moderate frequencies. The active vibration absorber is very effective in suppressing both on-orbit and lift-off vibration environments. Dissert. Abstr.

OPERATION OF THE COMPUTER MODEL FOR DIRECT ATOMIC OXYGEN EXPOSURE OF EARTH SATELLITES

R. J. Bourassa, P. E. Gruenbaum, J. R. Gillis, and C. R. Hargraves Aug. 1995 112 p

(Contracts NAS1-18224; NAS1-19247; RTOP 233-03-02-02)

(NASA-CR-198188; NAS 1.26:198188) Avail: CASI HC A06/MF A02

One of the primary causes of material degradation in low Earth orbit (LEO) is exposure to atomic oxygen. When atomic oxygen molecules collide with an orbiting spacecraft, the relative velocity is 7 to 8 km/sec and the collision energy is 4 to 5 eV per atom. Under these conditions, atomic oxygen may initiate a number of chemical and physical reactions with exposed materials. These reactions contribute to material degradation, surface erosion, and contamination. Interpretation of these effects on materials and the design of space hardware to withstand on-orbit conditions requires quantitative knowledge of the atomic oxygen exposure environment. Atomic oxygen flux is a function of orbit altitude, the orientation of the orbit plan to the Sun, solar and geomagnetic activity, and the angle between exposed surfaces and the spacecraft heading. We have developed a computer model to predict the atomic oxygen exposure of spacecraft in low Earth orbit. The application of this computer model is discussed. Author

COMPUTATIONAL METHODS AND SOFTWARE SYSTEMS FOR DYNAMICS AND CONTROL OF LARGE SPACE STRUCTURES Final Report

K. C. Park, C. A. Felippa, C. Farhat, and E. Pramono Jul. 1990 265 p

(Grant NAG1-756)

(NASA-CR-199036; NAS 1.26:199036; CU-CSSC-90-17) Avail: CASI HC A12/MF A03

This final report on computational methods and software systems for dynamics and control of large space structures covers progress to date, projected developments in the final months of the grant, and conclusions. Pertinent reports and papers that have not appeared in scientific journals (or have not yet appeared in final form) are enclosed. The grant has supported research in two key areas of crucial importance to the computer-based simulation of large space structure. The first area involves multibody dynamics (MBD) of flexible space structures, with applications directed to deployment, construction, and maneuvering. The second area deals with advanced software systems, with emphasis on parallel processing. The latest research thrust in the second area, as reported here, involves massively parallel computers. SUPPLEMENTAL MULTILAYER INSULATION RESEARCH FACILITY

P. J. Dempsey and R. J. Stochl Jul. 1995 7 p Presented at the 1995 Cryogenic Engineering Conference, Columbus, OH, 17-21 Jul. 1995; sponsored by Centennial Conferences

(RTOP 243-30-07)

(NASA-TM-106991; E-9766; NAS 1.15:106991) Avail: CASI HC A02/MF A01

The Supplemental Multilayer Insulation Research Facility (SMIRF) provides a small scale test bed for conducting cryogenic experiments in a vacuum environment. The facility vacuum system is capable of simulating a Space Shuttle launch pressure profile as well as providing a steady space vacuum environment of 1.3 x 10(exp -4) Newton/sq meter (1 x 10(exp -6) torr). Warm side boundary temperatures can be maintained constant between 111 K (200 R) and 361 K (650 R) using a temperature controlled shroud. The shroud can also simulate a typical lunar day-night temperature profile. The test hardware consists of a cryogenic calorimeter supported by the lid of the vacuum chamber. A 0.45 cu meter (120 gallon) vacuum jacketed storage/supply tank is available for conditioning the cryogen prior to use in the calorimeter. The facility was initially designed to evaluate the thermal performance of insulation systems for long-term storage in space. The facility has recently been used to evaluate the performance of various new insulation systems for LH2 and LN2 ground storage dewars. Author

ELECTRICALLY HEATED TUBE INVESTIGATION OF COOLING CHANNEL GEOMETRY EFFECTS

Michael L. Meyer Jun. 1995 14 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; sponsored by AIAA, ASME, SAE and ASEE

(NASA-TM-106985; E-9760; NAS 1.15:106985; AIAA Paper 95-2500) Avail: CASI HC A03/MF A01

The results of an experimental investigation on the combined effects of cooling channel aspect ratio and curvature for rocket engines are presented. Symmetrically heated tubes with average heat fluxes up to 1.7 MW/m(exp 2) were used. The coolant was gaseous nitrogen at an inlet temperature of 280 K (500 R) and inlet pressures up to 1.0 x 10(exp 7) N/m(exp 2) (1500 psia). Two different tube geometries were tested: a straight, circular cross-section tube, and an aspect-ratio 10 cross-section tube with a 45 deg bend. The circular tube results are compared to classical models from the literature as validation of the system. The curvature effect data from the curved aspect-ratio 10 tube compare favorably to the empirical equations available in the literature for low aspect ratio tubes. This latter results suggest that thermal stratification of the coolant due to diminished curvature effect mixing may not be an issue for high aspect-ratio cooling channels. Author

EFFECTS OF THERMAL AND ELECTRICAL STRESSING ON THE BREAKDOWN BEHAVIOR OF SPACE WIRING Final Report

Ahmad Hammoud, Mark Stavnes, Jayant Suthar (State Univ. of New York, Buffalo, NY.), and Javaid Laghari (State Univ. of New York, Buffalo, NY.) Jun. 1995 6 p

(Contract NAS3-27186; NAG3-1345; RTOP 297-50-00)

(NASA-CR-198360; E-9750; NAS 1.26:198360) Avail: CASI HC A02/MF A01

Several failures in the electrical wiring systems of many aircraft and space vehicles have been attributed to arc tracking and damaged insulation. In some instances, these failures proved to be very costly as they have led to the loss of many aircraft and imperilment of space missions. Efforts are currently underway to develop lightweight, reliable, and arc track resistant wiring for aerospace applications. In this work, six wiring constructions were evaluated in terms of their breakdown behavior as a function of temperature. These hybrid constructions employed insulation consisting of Kapton, Teflon, and cross-linked Tefzel. The properties investigated included the 400 Hz AC dielectric strength at ambient and 200 C, and the lifetime at high temperature with an applied bias of 40, 60, and 80% of breakdown voltage level. The results obtained are discussed, and conclusions are made concerning the suitability of the wiring constructions investigated for aerospace applications. Author

KINETIC THEORY MODEL PREDICTIONS COMPARED WITH LOW-THRUST AXISYMMETRIC NOZZLE PLUME DATA

B. R. Riley (Evansville Univ., IN.), S. J. Fuhrman (Evansville Univ., IN.), and P. F. Penko American Inst. of Aeronautics and Astronautics 1993 9 p

(Grant NAG3-746)

(NASA-CR-198934; NAS 1.26:198934) Avail: CASI HC A02/MF A01

A system of nonlinear integral equations equivalent to the steady-state Krook kinetic equation was used to model the flow from a low-thrust axisymmetric nozzle. The mathematical model was used to numerically calculate the number density, temperature, and velocity of a simple gas as it expands into a near vacuum. With these quantities the gas pressure and flow directions of the gas near the exit plane were calculated and compared with experimental values for a low-thrust nozzle of the same geometry and mass flow rate. ADVANCED SMALL ROCKET CHAMBERS. OPTION 3: 110 lbf Ir-Re ROCKET, VOLUME 1 Final Report

Donald M. Jassowski and Leonard Schoenman Feb. 1995 390 p
(Contract NAS3-25646; RTOP 242-70-02)
(NASA-CR-195435-Vol-1; E-9457-Vol-1; NAS 1.26:195435-Vol-1) Avail: CASI HC A17/MF A04

This report describes the AJ10-221, a high performance Iridium-coated Rhenium (Ir-Re) 110 lbf (490N) welded rocket chamber with 286:1 area ratio nozzle. This engine was designed, built, and hot fired for over 6 hours on this program. It demonstrated an I(s) of 321.8 sec, which is 10 sec higher than conventional 110 lbf silicide coated Cb chambers now in use. The approach used in this portion of the program was to demonstrate the performance improvement that can be made by the elimination of fuel film cooling and the use of a high temperature (4000F) (2200C) iridium-coated rhenium (Ir-Re) rocket chamber. Detailed thermal, performance, mechanical, and dynamic design analyses of the full engine were conducted by Aerojet. Two Ir-Re chambers were built to the Aerojet design by Ultramet, using the chemical vapor deposition (CVD) process. Incorporation of a secondary mixing device or Boundary Layer Trip (BLT) within the combustion chamber (Aerojet Patents 4882904 and 4936091) results in improvement in flow uniformity, and a significant life and performance increase. The 110 lbf engine design was verified in bolt-up hardware tests at sea level and altitude. The effects of injector design on performance were studied. Two duplicate injectors were fabricated matching the preferred design and were demonstrated to be interchangeable in operation. One of these units was fabricated matching the preferred design and was demonstrated to be interchangeable in operation. One of these units was welded into a flight type thruster which was tested for an accumulated duration of 22,590 sec in 93 firings, one of which was a continuous burn of two hours. A design deficiency in the C-103 nozzle near the Re-Cb transition joint was discovered, studied and corrected design has been prepared. Workhardening studies have been conducted to investigate methods for increasing the low yield strength of the Re in the annealed conditions. An advanced 490N high performance engine has been demonstrated which, when proven to be capable of withstanding launch vibration, is ready for flight qualification.

(AD-A293654; TR-94(4507)-1; SMC-TR-95-13) Avail: CASI HC A03/MF A01

Thrust vector stability for an electrostatic ion engine can be measured with improved sensitivity and time resolution by the method described here. Four double-wire Langmuir probes, aligned in the form of a cross, are placed in the exhaust plume and are translated by a motorized positioning system to balance the currents collected along two orthogonal axes. The thrust vector position is thereby measured with an angular resolution of less than 0.01 deg and a response time of less than 5 sec. DTIC

PRIMARY ATOMIZATION OF LIQUID JETS ISSUING FROM ROCKET ENGINE COAXIAL INJECTORS Ph.D. Thesis
Roger D. Woodward 1993 178 p
Avail: Univ. Microfilms Order No. DA9414399

The investigation of liquid jet breakup and spray development is critical to the understanding of combustion phenomena in liquid-propellant rocket engines. Much work has been done to characterize low-speed liquid jet breakup and dilute sprays, but atomizing jets and dense sprays have yielded few quantitative measurements due to their optical opacity. This work focuses on a characteristic of the primary breakup process of round liquid jets, namely the length of the intact liquid core. The specific application considered is that of shear-coaxial type rocket engine injectors. Real-time x-ray radiography, capable of imaging through the dense two-phase region surrounding the liquid core, has been used to make the measurements. Nitrogen and helium were employed as the fuel simulants while an x-ray absorbing potassium iodide aqueous solution was used as the liquid oxygen (LOX) simulant. The intact-liquid-core length data have been obtained and interpreted to illustrate the effects of chamber pressure (gas density), injected-gas and liquid velocities, and cavitation. The results clearly show that the effect of cavitation must be considered at low chamber pressures since it can be the dominant breakup mechanism. A correlation of intact core length in terms of gas-to-liquid density ratio, liquid jet Reynolds number, and Weber number is suggested. The gas-to-liquid density ratio appears to be the key parameter for aerodynamic shear breakup in this study. A small number of hot-fire, LOX/hydrogen tests were also conducted to attempt intact-LOX-core measurements under realistic conditions in a single-coaxial-element rocket engine. The tests were not successful in terms of measuring the intact core, but instantaneous imaging of LOX jets suggests that LOX jet breakup is qualitatively similar to that of cold-flow, propellant-simulant jets. The liquid oxygen jets survived in the hot-fire environment much longer than expected, and LOX was even visualized exiting the chamber nozzle under some conditions. This may be an effect of the single element configuration. Dissert. Abstr.

EXPERIMENT OF ROCKET-RAM COMBINED COMBUSTOR
Kazuo Sato, Hiroshi Sakamoto, Masaki Sasaki, Fumiei Ono, and Nobuyuki Yatsuyanagi Oct. 1994 20 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1249) Avail: CASI HC A03/MF A01

There are limitations to achieve high specific impulse with rocket engine operations alone. However, in the flight at low altitude, combined engines with an airbreathing ramjet engine and a rocket engine can be expected to increase the specific impulse significantly in parallel operation. In this paper, the superiority in the specific impulse of the double-nozzle type of rocket-ram combined engine over the single-nozzle type combined engine was shown by performance calculations. Then, a double-nozzle type of rocket-ram combined combustor with a total thrust of 5kN was designed and experimentally tested with varying ratios of thrust produced by rocket and ramjet. The propellants are LOX/kerosene+ hydrogen for rocket combustion and air-hydrogen for ram combustion. With the thrust chamber having different diverging half-angles, namely 10 deg 18 min, and 6 deg 40 min, thrust and pressure distribution along the common expansion nozzle were measured to investigate the effect of interaction of the expanding gases of rocket and ram on thrust. Enhancement of the specific impulse was experimentally verified. That is, the specific impulse which was gained

in rocket-ram parallel operations, when the thrust ratio of rocket to ram was 50 to 50, was found to increase 90 percent over those in pure rocket operations. Author

N95-31972 Colorado Univ., Boulder, CO.
COMBUSTION RESPONSE TO ACOUSTIC PERTURBATION IN LIQUID ROCKET ENGINES Ph.D. Thesis
Akbar Ghafourian 1993 169 p
Avail: Univ. Microfilms Order No. DA9423489

An experimental study of the effect of acoustic perturbations on combustion behavior of a model liquid propellant rocket engine has been carried out. A pair of compression drivers were used to excite transverse and longitudinal acoustic fields at strengths of up to 156.6 dB and 159.5 dB respectively in the combustion chamber of the experimental rocket engine. Propellant simulants were injected into the combustion chamber through a single element shear coaxial injector. Water and air were used in cold flow studies and ethanol and oxygen-enriched air were used as fuel and oxidizer in reacting hot flow studies. In cold flow studies an imposed transverse acoustic field had a more pronounced effect on the spray pattern than a longitudinal acoustic fields. A transverse acoustic field widened the spray by as much as 33 percent and the plane of impingement of the spray with chamber walls moved up closer to the injection plane. The behavior was strongly influenced by the gas phase velocity but was less sensitive to changes in the liquid phase velocity. In reacting hot flow studies the effects of changes in equivalence ratio, excitation amplitude, excitation frequency, liquid and gas phase velocity and chamber pressure on the response of the injector to imposed high frequency transverse acoustic excitation were measured. Reducing the equivalence ratio from 7.4 to 3.8 increased the chamber pressure response to the imposed excitation at 3000 Hz. Increasing the excitation amplitude from 147 dB to 155.6 dB at 3000 Hz increased the chamber pressure response to the excitation. In the frequency range of 1240 Hz to 3220 Hz, an excitation frequency of 3000 Hz resulted in the largest response of the chamber pressure indicating the importance of fluid dynamic coupling. Increasing the liquid phase velocity from 9.2 m/sec to 22.7 m/sec, did not change the amplitude of the chamber pressure response to excitation. This implied the importance of local equivalence ratio and not the overall equivalence ratio on chamber pressure response to excitation. Increasing the chamber pressure from 1.5 atm to 3.1 atm and gas phase velocity from 93.2 m/sec to 105.1 m/sec significantly increased the chamber pressure response to acoustic excitation. This emphasized the significance of the gas phase density and velocity. Measurements of the free radical C2 emission zone and Schlieren images indicated that transverse acoustic excitation moved the combustion zone closer to the injection plane and longitudinal acoustic excitation widened the combustion zone. The histogram of these images indicates that the area over which combustion takes place in the chamber increases under imposed acoustic excitation. This implied that more propellants combust prior to exiting from the exhaust nozzle under unsteady conditions. Dissert. Abstr.

ROBUST ROCKET ENGINE CONCEPT
Carl F. Lorenzo Jul. 1995 11 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; cosponsored by AIAA, ASME, SAE, and ASEE
(RTOP 505-62-50)
(NASA-TM-107010; E-9794; NAS 1.15:107010) Avail: CASI HC A03/MF A01

The potential for a revolutionary step in the durability of reusable rocket engines is made possible by the combination of several emerging technologies. The recent creation and analytical demonstration of life extending (or damage mitigating) control technology enables rapid rocket engine transients with minimum fatigue and creep damage. This technology has been further enhanced by the formulation of very simple but conservative continuum damage models. These new ideas when combined with recent advances in multidisciplinary optimization provide the potential for a large (revolutionary) step in reusable rocket engine durability. This concept has been named the robust rocket engine concept (RREC) and is the basic contribution of this paper. The concept also includes consideration of design innovations to minimize critical point damage. Author

The new compound diisopropyl stibine is prepared by reacting an diisopropyl antimony halide with a hydride or deuteride transferring agent. The reaction is preferably carried out below about 0 C, in an inert atmosphere, under darkened conditions. The diisopropyl stibine is used as a precursor in forming antimony-containing semiconductor material by chemical vapor deposition. DTIC

ENANTIOSELECTIVITY OF QUINOPROTEIN ALCOHOL DEHYDROGENASES: PRODUCTION OF ENANTIOMERICALLY PURE C3-ALCOHOL SYNTHONS Ph.D. Thesis
Arie Geerlof 27 Sep. 1994 153 p
(PB95-196960) Avail: CASI HC A08/MF A02

The aim of this thesis was to investigate the possibility of using alcohol oxidoreductases as catalyst in the kinetic resolution of racemic mixtures of alcohols. Therefore, a screening was performed to determine the enantioselectivity in the oxidation of a number of chiral alcohols by alcohol dehydrogenases (ADH's) and oxidases. In view of the availability of and know-how on quinoprotein (pyrroloquinoline quinone (PQQ)-containing) alcohol dehydrogenases (Q-ADH's) in the authors' laboratory, the attention was especially focussed on these enzymes. Three independent studies have been conducted for assessing the impact of rocket launches on the earth's environment. These studies have addressed issues of acid rain in the troposphere, ozone depletion in the stratosphere, toxicity of chemical rocket exhaust products, and the potential impact on global warming from carbon dioxide emissions from rocket launches. Local, regional, and global impact assessments were examined and compared with both natural sources and anthropogenic sources of known atmospheric pollutants with the following conclusions: (1) Neither solid nor liquid rocket launches have a significant impact on the earth's global environment, and there is no real significant difference between the two. (2) Regional and local atmospheric impacts are more significant than global impacts, but quickly return to normal background conditions within a few hours after launch. And (3) vastly increased space launch activities equivalent to 50 U.S. Space Shuttles or 50 Russian Energia launches per year would not significantly impact these conclusions. However, these assessments, for the most part, are based upon homogeneous gas phase chemistry analysis; heterogeneous chemistry from exhaust particulates, such as aluminum oxide, ice contrails, soot, etc., and the influence of plume temperature and afterburning of fuel-rich exhaust products, need to be further addressed. It was the consensus of these studies that computer modeling of interactive plume chemistry with the atmosphere needs to be improved and computer models need to be verified with experimental data. Rocket exhaust plume chemistry can be modified with propellant reformulation and changes in operating conditions, but, based upon the current state of knowledge, it does not appear that significant environmental improvements from propellant formulation changes can be made or are warranted. Flight safety, reliability, and cost improvements are paramount for any new rocket system, and these important aspects cannot be compromised. A detailed environmental cost-benefit-risk analysis must be conducted before any new chemistry or changes in rocket operating conditions should be seriously considered for any future space or defense applications. This paper presents a summary of the results of environmental assessments contained in these independent studies. Author

The waste production, mitigation and disposal practices of the United States chemical propulsion industry have been investigated, delineated, and comparatively assessed to the U.S. industrial base. Special emphasis has been placed on examination of ozone depleting chemicals (ODC's). The research examines present and anticipated future practices and problems encountered in the manufacture of solid and liquid propulsion systems. Information collected includes current environmental laws and

regulations that guide the industry practices, processes in which ODC's are or have been used, quantities of waste produced, funding required to maintain environmentally compliant practices, and preventive efforts.

CFD ASSESSMENT OF THE POLLUTANT ENVIRONMENT FROM RD-170 PROPULSION SYSTEM TESTING **c45**
Ten-See Wang, Paul McConnaughey, Saif Warsi (Sverdrup Technology, Inc., Huntsville, AL.), and Yen-Sen Chen (Engineering-Science, Inc., Huntsville, AL.) *In its* Aerospace Environmental Technology Conference Mar. 1995 p 25-47 (For primary document see N95-31746 11-23)
Avail: CASI HC A03/MF A06

Computational Fluid Dynamics (CFD) technology has been used to assess the exhaust plume pollutant environment of the RD-170 engine hot-firing on the F1 Test Stand at Marshall Space Flight Center. Researchers know that rocket engine hot-firing has the potential for forming thermal nitric oxides (NO(x)), as well as producing carbon monoxide (CO) when hydrocarbon fuels are used. Because of the complicated physics involved, however, little attempt has been made to predict the pollutant emissions from ground-based engine testing, except for simplified methods which can grossly underpredict and/or overpredict the pollutant formations in a test environment. The objective of this work, therefore, has been to develop a technology using CFD to describe the underlying pollutant emission physics from ground-based rocket engine testing. This resultant technology is based on a three-dimensional (3D), viscous flow, pressure-based CFD formulation, where wet CO and thermal NO finite-rate chemistry mechanisms are solved with a Penalty Function method. A nominal hot-firing of a RD-170 engine on the F1 stand has been computed. Pertinent test stand flow physics such as the multiple-nozzle clustered engine plume interaction, air aspiration from base and aspirator, plume mixing with entrained air that resulted in contaminant dilution and afterburning, counter-afterburning due to flame bucket water-quenching, plume impingement on the flame bucket, and restricted multiple-plume expansion and turning have been captured. The predicted total emission rates compared reasonably well with those of the existing hydrocarbon engine hot-firing test data. Author

This paper identifies the necessity of chemical propulsion to satellite usage and some of the benefits accrued through monitoring global resources and patterns, including the Global Climate Change Model (GCM). The paper also summarized how the satellite observations are used to affect national and international policies. Chemical propulsion, like all environmentally conscious industries, does provide limited, controlled pollutant sources through its manufacture and usage. However, chemical propulsion is the sole source which enables mankind to launch spacecraft and monitor the Earth. The information provided by remote sensing directly affects national and international policies designed to protect the environment and enhance the overall quality of life on Earth. The resultant of chemical propulsion is the capability to reduce overall pollutant emissions to the benefit of mankind. Derived from text

A solid propellant ingredient reclamation pilot plant has been evaluated at the Strategic Operations of Thiokol Corporation, located in Brigham City, Utah. The plant produces AP wet cake (95 percent AP, 5 percent water) for recycling at AP vendors. AP has been obtained from two standard propellant binder systems (PBAN and HTPB). Analytical work conducted at Thiokol indicates that the vendor-recrystallized AP meets Space Shuttle propellant specification requirements. Thiokol has processed 1-, 5-, and 600-gallon propellant mixes with the recrystallized AP. Processing, cast, cure, ballistic, mechanical, and safety properties have been evaluated. Phillips Laboratory static-test-fired 70-pound and 800-pound BATES motors. The data indicate that propellant processed with reclaimed AP has nominal properties. Author

Large amounts of energetic materials which have been accumulated over the years in various manufacturing and military installations must be disposed of in an environmentally sound manner. Historically, the method of choice for destruction of obsolete or aging energetic materials has been open burning or open detonation (OB/OD). This destruction approach has become undesirable due to air pollution problems. Therefore, there is a need for new technologies which will effectively and economically deal with the disposal of energetic materials. Along those lines, we have investigated a chemical/biological process for the safe destruction and disposal of a double base solid rocket propellant (AHH), which was used in several 8 inch projectile systems. The solid propellant is made of nitrocellulose and nitroglycerin as energetic components, two lead salts which act as ballistic modifiers, triacetin as a plasticizer and 2-Nitrodiphenylamine (2-NDPA) as a stabilizer. A process train is being developed to convert the organic components of the propellant to biodegradable products and remove the lead from the process stream. The solid propellant is first hydrolyzed through an enhanced alkaline hydrolysis process step. Following lead removal and neutralization, the digested liquor rich in nitrates and nitrites is found to be easily biodegradable. The digestion rate of the intact ground propellant as well as the release of nitrite and nitrate groups were substantially increased when ultrasound were supplied to the alkaline reaction medium compared to the conventional alkaline hydrolysis. The effects of reaction time, temperature, sodium hydroxide concentration and other relevant parameters on the digestion efficiency and biodegradability have been studied. The present work indicates that the AHH propellant can be disposed of safely with a combination of physiochemical and biological processes. Author

Hercules' clean propellant development research is exploring three major types of clean propellant: (1) chloride-free formulations (no chlorine containing ingredients), being developed on the Clean Propellant Development and Demonstration (CPDD) contract sponsored by Phillips Laboratory, Edwards Air Force Base, CA; (2) low HCl scavenged formulations (HCl-scavenger added to propellant oxidized with ammonium perchlorate (AP)); and (3) low HCl formulations oxidized with a combination of AN and AP (with or without an HCl scavenger) to provide a significant reduction (relative to current solid rocket boosters) in exhaust HCl. These propellants provide performance approaching that of current systems, with less than 2 percent HCl in the exhaust, a significant reduction (greater than or equal to 70 percent) in exhaust HCl levels. Excellent processing, safety, and mechanical properties were achieved using only readily available, low cost ingredients. Two formulations, a sodium nitrate (NaNO3) scavenged HTPB and a chloride-free hydroxy terminated polyether (HTPE) propellant, were characterized for ballistic, mechanical, and rheological properties. In addition, the hazards properties were demonstrated to provide two families of class 1.3, 'zero-card' propellants. Further characterization is planned which includes

demonstration of ballistic tailorability in subscale (one to 70 pound) motors over the range of burn rates required for retrofit into current Hercules space booster designs (Titan 4 SRMU and Delta 2 GEM). Author

The potential environmental effects of the exhaust products of conventional rocket propellants have been assessed by various groups. Areas of concern have included stratospheric ozone, acid rain, toxicity, air quality and global warming. Some of the studies which have been performed on this subject have concluded that while the impacts of rocket use are extremely small, there are propellant development options which have the potential to reduce those impacts even further. This paper discusses the various solid propellant options which have been proposed as being more environmentally benign than current systems by reducing HCl emissions. These options include acid neutralized, acid scavenged, and nonchlorine propellants. An assessment of the acid reducing potential and the viability of each of these options is made, based on current information. Such an assessment is needed in order to judge whether the potential improvements justify the expenditures of developing the new propellant systems. Author

McDonnell Douglas Aerospace, as part of its Independent R&D, has initiated development of a clean burning, high performance hybrid fuel for consideration as an alternative to the solid rocket thrust augmentation currently utilized by American space launch systems including Atlas, Delta, Pegasus, Space Shuttle, and Titan. It could also be used in single stage to orbit or as the only propulsion system in a new launch vehicle. Compared to solid propellants based on aluminum and ammonium perchlorate, this fuel is more environmentally benign in that it totally eliminates hydrogen chloride and aluminum oxide by products, producing only water, hydrogen, nitrogen, carbon oxides, and trace amounts of nitrogen oxides. Compared to other hybrid fuel formulations under development, this fuel is cheaper, denser, and faster burning. The specific impulse of this fuel is comparable to other hybrid fuels and is between that of solids and liquids. The fuel also requires less oxygen than similar hybrid fuels to produce maximum specific impulse, thus reducing oxygen delivery system requirements. Author

This paper is a survey of the waste minimization efforts of industries outside of aerospace for possible applications in the manufacture of solid rocket motors (SRM) for NASA. The Redesigned Solid Rocket Motor (RSRM) manufacturing plan was used as the model for processes involved in the production of an SRM. A literature search was conducted to determine the recycling, waste minimization, and waste treatment methods used in the commercial sector that might find application in SRM production. Manufacturers, trade organizations, and professional associations were also contacted. Waste minimization efforts for current processes and replacement technologies, which might reduce the amount or severity of the wastes generated in SRM production, were investigated. An overview of the results of this effort are presented in this paper. Author

PRIORITIZATION METHODOLOGY FOR CHEMICAL REPLACEMENT **c45**
Wendy Cruit, Ben Goldberg, and Scott Schutzenhofer *In its* Aerospace Environmental Technology Conference Mar. 1995 p 131-141 (For primary document see N95-31746 11-23)
Avail: CASI HC A03/MF A06

Since United States of America federal legislation has required ozone depleting chemicals (class 1 & 2) to be banned from production, The National Aeronautics and Space Administration (NASA) and industry have been required to find other chemicals and methods to replace these target chemicals. This project was initiated as a development of a prioritization methodology suitable for assessing and ranking existing processes for replacement 'urgency.' The methodology was produced in the form of a workbook (NASA Technical Paper 3421). The final workbook contains two tools, one for evaluation and one for prioritization. The two tools are interconnected in that they were developed from one central theme - chemical replacement due to imposed laws and regulations. This workbook provides matrices, detailed explanations of how to use them, and a detailed methodology for prioritization of replacement technology. The main objective is to provide a GUIDELINE to help direct the research for replacement technology. The approach for prioritization called for a system which would result in a numerical rating for the chemicals and processes being assessed. A Quality Function Deployment (QFD) technique was used in order to determine numerical values which would correspond to the concerns raised and their respective importance to the process. This workbook defines the approach and the application of the QFD matrix. This technique: (1) provides a standard database for technology that can be easily reviewed, and (2) provides a standard format for information when requesting resources for further research for chemical replacement technology. Originally, this workbook was to be used for Class 1 and Class 2 chemicals, but it was specifically designed to be flexible enough to be used for any chemical used in a process (if the chemical and/or process needs to be replaced). The methodology consists of comparison matrices (and the smaller comparison components) which allow replacement technology to be quantitatively compared in several categories, and a QFD matrix which allows process/chemical pairs to be rated against one another for importance (using consistent categories). Depending on the need for application, one can choose the part(s) needed or have the methodology completed in its entirety. For example, if a program needs to show the risk of changing a process/chemical one may choose to use part of Matrix A and Matrix C. If a chemical is being used, and the process must be changed; one might use the Process Concerns part of Matrix D for the existing process and all possible replacement processes. If an overall analysis of a program is needed, one may request the QFD to be completed. Author

The Titan 4 Space Launch Vehicle Program is one of many major weapon system programs that have modified acquisition plans and operational procedures to meet new, stringent environmental rules and regulations. The Environmental Protection Agency (EPA) and the Department of Defense (DOD) mandate to reduce the use of ozone depleting chemicals (ODC's) is just one of the regulatory changes that has affected the program. In the last few years, public environmental awareness, coupled with stricter environmental regulations, has created the need for DOD to produce environmental life-cycle cost estimates (ELCCE) for every major weapon system acquisition program. The environmental impact of the weapon system must be assessed and budgeted, considering all costs, from cradle to grave. The Office of the Secretary of Defense (OSD) has proposed that organizations consider Conservation, Cleanup, Compliance and Pollution Prevention (C(sup 3)P(sup 2)) issues associated with each acquisition program to assess life-cycle impacts and costs. The Air Force selected the Titan 4 system as the pilot program for estimating life-cycle environmental costs. The estimating task required participants to develop an ELCCE methodology, collect data to test the methodology and produce a credible cost estimate within the DOD C(sup 3)P(sup 2) definition. The estimating methodology included using the Program Office weapon system description and work breakdown structure together with operational site and manufacturing plant visits to identify environmental cost drivers. The results of the Titan IV ELCCE process are discussed and expanded to demonstrate how they can be applied to satisfy any life-cycle environmental cost estimating requirement. Author

EVALUATING THE COST EFFECTIVENESS OF ENVIRONMENTAL PROJECTS: CASE STUDIES IN AEROSPACE AND DEFENSE c45

James F. Shunk *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 169-177 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

Using the replacement technology of high pressure waterjet decoating systems as an example, a simple methodology is presented for developing a cost effectiveness model. The model uses a four-step process to formulate an economic justification designed for presentation to decision makers as an assessment of the value of the replacement technology over conventional methods. Three case studies from major U.S. and international airlines are used to illustrate the methodology and resulting model. Tax and depreciation impacts are also presented as potential additions to the model. Author

THE OAK RIDGE REFRIGERANT MANAGEMENT PROGRAM c27

Thomas H. Kevil *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 179-186 (For primary document see N95-31746 11-23)

(Contract DE-AC05-84OR-21400)

Avail: CASI HC A02/MF A06

For many years, chlorofluorocarbons (CFC's) have been used by the Department of Energy's (DOE) Oak Ridge Y-12 Plant in air conditioning and process refrigeration systems. However, Title 6 of the Clean Air Act Amendments (CAAA) and Executive Order 12843 (Procurement Requirements and Policies for Federal Agencies for Ozone Depleting Substances) signed by President Clinton require, as policy, that all federal agencies maximize their use of safe, alternate refrigerants and minimize, where economically practical, the use of Class 1 refrigerants. Unfortunately, many government facilities and industrial plants have no plan or strategy in place to make this changeover, even though their air conditioning and process refrigeration equipment may not be sustainable after CFC production ends December 31, 1995. The Y-12 Plant in Oak Ridge, Tennessee, has taken an aggressive approach to complying with the CAAA and is working with private industry and other government agencies to solve tough manufacturing and application problems associated with CFC and hydrochlorofluorocarbon (HCFC) alternatives. Y-12 was the first DOE Defense Program (DP) facility to develop a long-range Stratospheric Ozone Protection Plan for refrigerant management for compliance with the CAAA. It was also the first DOE DP facility to complete detailed engineering studies on retrofitting and replacing all air conditioning and process refrigeration equipment to enable operation with alternate refrigerants. The management plan and engineering studies are models for use by other government agencies, manufacturing plants, and private industry. This presentation identifies some of the hidden pitfalls to be encountered in the accelerated phaseout schedule of CFC's and explains how to overcome and prevent these problems. In addition, it outlines the general issues that must be considered when addressing the phase-out of ozone depleting substances and gives some 'lessons learned' by Y-12 from its Refrigerant Management Program. Discussion topics include requirements for developing a refrigerant management plan and establishing priorities for cost-effective compliance with the CAAA, as well as ways in which employees can be empowered to develop a comprehensive refrigerant management plan. The result of this employee empowerment was a cooperative labor-management effort that is beneficial for Y-12, DOE, and the environment. Author

Prepsolv (TM): THE OPTIMUM ALTERNATIVE TO 1,1,1-TRICHLOROETHANE AND METHYL ETHYL KETONE FOR HAND-WIPE CLEANING OF AEROSPACE MATERIALS c27

R. Scott Gallagher, John A. Purvis (Hercules Aerospace Co., Magna, UT.), and Wade W. Moran (Hercules Aerospace Co., Magna, UT.) *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 187-197 (For primary document see N95-31746 11-23)

Avail: CASI HC A03/MF A06

Engineers at Hercules Aerospace, a rocket motor manufacturer in Utah, have worked closely with chemists at Glidco Organics to study the feasibility of using terpenes for zero-residue wipe cleaning. The result of this work is a technological breakthrough, in which the barrier to ultra-low non-volatile residue formation has been broken. After 2 years of development and testing, SCM Glidco Organics has announced the availability of Glidsafe(registered trademark) Prepsolv(TM): a state-of-the-art ultra-low residue terpene wipe cleaning agent that does not require rinsing. Prepsolv(TM) can successfully be used in simple hand-wipe cleaning processes without fear of leaving surface residues. Industry testing has confirmed that Prepsolv(TM) is not only highly effective, but can even be less expensive to use than traditional cleaning solvents like methyl chloroform. This paper addresses the features and benefits of Prepsolv(TM), and presents performance and material compatibility data that characterizes

this unique cleaning agent. Since its commercialization, Hercules Aerospace has chosen Prepsolv(TM) as the optimum cleaning agent to replace ozone-depleting solvents in their weapons factory in Magna, UT. Likewise, Boeing has approved Prepsolv(TM) for cleaning components in the manufacture of commercial aircraft at their facilities in Seattle, WA and Wichita, KS. Additional approvals are forthcoming for this uniquely safe and effective solvent. Derived from text

A WATER BLOWN URETHANE INSULATION FOR USE IN CRYOGENIC ENVIRONMENTS **c27**
Elana Blevins and Jon Sharpe *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 201-206 (For primary document see N95-31746 11-23)
(Contract NAS8-36200)
Avail: CASI HC A02/MF A06

Thermal Protection Systems (TPS) of NASA's Space Shuttle External Tank include polyurethane and polyisocyanurate modified polyurethane foam insulations. These insulations, currently foamed with CFC 11 blowing agent, serve to maintain cryogenic propellant quality, maintain the external tank structural temperature limits, and minimize the formation of ice and frost that could potentially damage the ceramic insulation on the space shuttle orbiter. During flight the external tank insulations are exposed to mechanical, thermal and acoustical stresses. TPS must pass cryogenic flexure and substrate adhesion tests at -253 C, aerothermal and radiant heating tests at fluxes up to approximately 14 kilowatts per square meter, and thermal conductivity tests at cryogenic and elevated temperatures. Due to environmental concerns, the polyurethane insulation industry and the External Tank Project are tasked with replacing CFC 11. The flight qualification of foam insulations employing HCFC 141b as a foaming agent is currently in progress; HCFC 141b blown insulations are scheduled for production implementation in 1995. Realizing that the second generation HCFC blowing agents are an interim solution, the evaluation of third generation blowing agents with zero ozone depletion potential is underway. NASA's TPS Materials Research Laboratory is evaluating third generation blowing agents in cryogenic insulations for the External Tank; one option being investigated is the use of water as a foaming agent. A dimensionally stable insulation with low friability, good adhesion to cryogenic substrates, and acceptable thermal conductivity has been developed with low viscosity materials that are easily processed in molding applications. The development criteria, statistical experimental approach, and resulting foam properties will be presented. Author

Avail: CASI HC A03/MF A06

Hydrochlorofluorocarbon (HCFC) 141b has been selected as the interim blowing agent for use in urethane insulations on NASA's Space Shuttle External Tank. Due to the expected limited commercial lifetime of this material, research efforts at the NASA Thermal Protection Systems Materials Research Laboratory at the Marshall Space Flight Center are now being devoted to the identification and development of alternatives with zero ozone depletion potential. Physical blowing agents identified to date have included hydrocarbons, fluorocarbons, hydrofluoroethers, and more predominantly, hydrofluorocarbons (HFCs). The majority of the HFC evaluations in industry have focused on the more readily available, low boiling candidates such as HFC 134a. Higher boiling HFC candidates that could be handled at ambient conditions and use current processing equipment would be more desirable. This paper will describe results from a research program of two such candidate HFC's performed as a cooperative effort between Martin Marietta Manned Space Systems, the U.S. Environmental Protection Agency, and Oak Ridge National Laboratories. The purpose of this effort was to perform a cursory evaluation of the developmental HFC's 245ca and 236ea as blowing agents in urethane based insulations. These two materials were selected from screening tests of 37 C2, C3, and C4 isomers based on physical properties, atmospheric lifetime, flammability, estimated toxicity, difficulty of synthesis, suitability for dual use as a refrigerant, and other factors. Solubility of the two materials in typical foam components was tested, pour foaming trials were performed, and preliminary data were gathered regarding foam insulation performance. Author

ALTERNATIVES TO OZONE DEPLETING REFRIGERANTS IN TEST EQUIPMENT **c27**
Richard L. Hall and Madeleine R. Johnson (Aerospace Guidance and Metrology Center, Newark Air Force Station, OH.) *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 225-232 (For primary document see N95-31746 11-23)
Avail: CASI HC A02/MF A06

This paper describes the initial results of a refrigerant retrofit project at the Aerospace Guidance and Metrology Center (AGMC) at Newark Air Force Base, Ohio. The objective is to convert selected types of test equipment to properly operate on hydrofluorocarbon (HFC) alternative refrigerants, having no ozone depleting potential, without compromising system reliability or durability. This paper discusses the primary technical issues and summarizes the test results for 17 different types of test equipment: ten environmental chambers, two ultralow temperature freezers, two coolant recirculators, one temperature control unit, one vapor degreaser, and one refrigerant recovery system. The postconversion performance test results have been very encouraging: system capacity and input power remained virtually unchanged. In some cases, the minimum operating temperature increased by a few degrees as a result of the conversion, but never beyond AGMC's functional requirements. Author

In response to the Air Force directive to remove Ozone Depleting Chemicals (ODC's) from military specifications and Defense Logistics Agency's Hazardous Waste Minimization Program, we are faced with how to ensure a quality aviation fuel without using such chemicals. Many of these chemicals are found throughout the fuel and fuel related military specifications and are part of test methods that help qualify the properties and quality of the fuels before they are procured. Many years ago there was a directive for military specifications to use commercially standard test methods in order to provide standard testing in private industry and government. As a result the test methods used in military specifications are governed by the American Society of Testing and Materials (ASTM). The Air Force has been very proactive in the removal or replacement of the ODC's and hazardous materials in these test methods. For example, ASTM D3703 (Standard Test Method for Peroxide Number of Aviation Turbine Fuels), requires the use of Freon 113, a known ODC. A new rapid, portable hydroperoxide test for jet fuels similar to ASTM D3703 that does not require the use of ODC's has been developed. This test has proved, in limited testing, to be a viable substitute method for ASTM D3703. The Air Force is currently conducting a round robin to allow the method to be accepted by ASTM and therefore replace the current method. This paper will describe the Air Force's initiatives to remove ODC's and hazardous materials from the fuel and fuel related military specifications that the Air Force Wright Laboratory. Author

Spectrex, Inc., located in Cedar Grove, NJ is a manufacturer of fire detection and suppression equipment. Spectrex is one of the original pioneers in high speed fire detection and suppression systems for combat vehicles. Spectrex has installed fire suppressions systems in thousands of combat

vehicles and ships throughout the world. Additionally, they manufacture flame explosion detectors, ship damage control systems, and optical gas and vapor detectors. The culmination of several years of research and development has recently produced an innovative electro-optical continuous monitoring systems called SharpEye 20/20I IR(sup 3) and SAFEYE that provide fast and reliable gas, vapor, aerosol, flame, and explosion detection. SharpEye 20/20I IR(sup 3) is a self-contained triple spectrum flame detector which scans for oscillating IR radiation (1 to 10 Hz) in the spectral bands ranging from 4.0 to 5.0 microns and uses programmed algorithms to check the ratio and correlation of data received by the three sensors to make the system highly immune to false alarms. It is extremely sensitive as it can detect a 1 x 1 square foot gasoline pan fire at 200 feet in less than 3 seconds. The sensitivity is user programmable, offering 4 ranges of detection. SAFEYE is comprised of a selected number of multispectral ban microprocessors controlled detectors which are in communication with one or more radiation sources that is projected along a 600 feet optical path. The signals from the selected narrow bands are processed and analyzed by highly sophisticated algorithms. It is ideal for high risk, remote, large areas such as petroleum and chemical manufacturing sites, waste dumps, aircraft cargo bays, and ship compartments. The SAFEYE will perform direct readings of the presence or rate of rise of concentrations of gases, vapors, or aerosols at the range of parts per million and provide alarms at various set points at different levels of concentrations. For more than two decades, halon 1301 has been protecting personnel and valuable aircraft and aerospace equipment from the hazards of fire. Only halon 1301 offered the advantages of being clean, odorless, colorless, electrically non-conductive and safe for occupied areas. However, concerns about the depletion of stratospheric ozone and the resulting Montreal Protocol mandated the production phase-out of halon 1301 on December 31, 1993. Prior to this phase-out, Great Lakes Chemical Corporation, the world's leading manufacturer of halon, directed substantial research efforts toward the rapid development of a safe, clean, and effective halon replacement. Some of the criteria for the development of a clean agent included: that it be an effective fire extinguisher; that it be safe for personnel; that it be safe for the environment; that it be safe for valuable assets; that it be cost effective; and that it be able to withstand the rigors of independent approvals. As the result of this research, Great Lakes developed FM-200(TM) is 1, 1, 1, 2, 3, 3, 3-hepta-fluoropropane. This paper discusses the physical properties of FM-200(TM) and its efficiency as an extinguishant. Author

Avail: CASI HC A03/MF A06

The National Center for Manufacturing Sciences (NCMS) is sponsoring an on-going project to assess pollution prevention and control technology available to the plating industry and to make this information available to those who can benefit from it. Completed project activities include extensive surveys of the plating industry and vendors of technologies and an indepth literature review. The plating industry survey was performed in cooperation with the National Association of Metal Finishers. The contractor that conducted the surveys and prepared the project products was CAI Engineering. The initial products of the project were made available in April, 1994. These products include an extensive report that presents the results of the surveys and literature review and an electronic database. The project results are useful for all those associated with pollution prevention and control in the plating industry. The results show which treatment, recovery and bath maintenance technologies have been most successful for different plating processes and the costs for purchasing and operating these technologies. The project results also cover trends in chemical substitution, the identification of compliance-problem pollutants, sludge generation rates, off-site sludge recovery and disposal options, and many other pertinent topics. THIN-FILM SULFURIC ACID ANODIZING AS A REPLACEMENT FOR CHROMIC ACID ANODIZING **c27**
K. J. Kallenborn and J. R. Emmons *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 267-276 (For primary document see N95-31746 11-23)
Avail: CASI HC A02/MF A06

Chromic acid has long been used to produce a thin, corrosion resistant (Type I) coating on aluminum. Following anodizing, the hardware was sealed using a sodium dichromate solution. Sealing closes up pores inherent in the anodized coating, thus improving corrosion resistance. The thinness of the brittle coating is desirable from a fatigue standpoint, and chromium was absorbed by the coating during the sealing process, further improving corrosion resistance. Unfortunately, both chromic acid and sodium dichromate contain carcinogenic hexavalent chromium. Sulfuric acid is being considered as a replacement for chromic acid. Sulfuric acid of 10-20 percent concentration has traditionally been used to produce relatively thick (Types II and III) or abrasion resistant (Type III) coatings. A more dilute, that is five weight percent, sulfuric acid anodizing process, which produces a thinner coating than Type II or III, with nickel acetate as the sealant has been developed. The process was evaluated in regard to corrosion resistance, throwing power, fatigue life, and processing variable sensitivity, and shows promise as a replacement for the chromic acid process. CADMIUM PLATING REPLACEMENTS **c27**
Mary J. Nelson and Earl C. Groshart *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 277-284 (For primary document see N95-31746 11-23)
Avail: CASI HC A02/MF A06

The Boeing Company has been searching for replacements to cadmium plate. Two alloy plating systems seem close to meeting the needs of a cadmium replacement. The two alloys, zinc-nickel and tin-zinc are from alloy plating baths; both baths are neutral pH. The alloys meet the requirements for salt fog corrosion resistance, and both alloys excel as a paint base. Currently, tests are being performed on standard fasteners to compare zinc-nickel and tin-zinc on threaded hardware where cadmium is heavily used. The Hydrogen embrittlement propensity of the zinc-nickel bath has been tested, and just beginning for the tin-zinc bath. Another area of interest is the electrical properties on aluminum for tin-zinc and will be discussed. The zinc-nickel alloy plating bath is in production in Boeing Commercial Airplane Group for non-critical low strength steels. The outlook is promising that these two coatings will help. The Boeing Company significantly reduce its dependence on cadmium plating. Author

ENVIRONMENTALLY REGULATED AEROSPACE COATINGS c27

Virginia L. Morris *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 295-305 (For primary document see N95-31746 11-23)

Avail: CASI HC A03/MF A06

Aerospace coatings represent a complex technology which must meet stringent performance requirements in the protection of aerospace vehicles. Topcoats and primers are used, primarily, to protect the structural elements of the air vehicle from exposure to and subsequent degradation by environmental elements. There are also many coatings which perform special functions, i.e., chafing resistance, rain erosion resistance, radiation and electric effects, fuel tank coatings, maskants, wire and fastener coatings. The scheduled promulgation of federal environmental regulations for aerospace manufacture and rework materials and processes will regulate the emissions of photochemically reactive precursors to smog and air toxics. Aerospace organizations will be required to identify, qualify and implement less polluting materials. The elimination of ozone depleting chemicals (ODC's) and implementation of pollution prevention requirements are added constraints which must be addressed concurrently. The broad categories of operations affected are the manufacture, operation, maintenance, and repair of military, commercial, general aviation, and space vehicles. The federal aerospace regulations were developed around the precept that technology had to be available to support the reduction of organic and air toxic emissions, i.e., the regulations cannot be technology forcing. In many cases, the regulations which are currently in effect in the South Coast Air Quality Management District (SCAQMD), located in Southern California, were used as the baseline for the federal regulations. This paper addresses strategies used by Southern California aerospace organizations to cope with these regulatory impacts on aerospace productions programs. All of these regulatory changes are scheduled for implementation in 1993 and 1994, with varying compliance dates established. Author

CONVERGENT SPRAY PROCESS FOR ENVIRONMENTALLY FRIENDLY COATINGS c27

Jack Scarpa *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 307-313 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

Conventional spray application processes have poor transfer efficiencies, resulting in an exorbitant loss in materials, solvents, and time. Also, with ever tightening Environmental Protection Agency (EPA) regulations and Occupational Safety and Health Administration requirements, the low transfer efficiencies have a significant impact on the quantities of materials and solvents that are released into the environment. High solids spray processes are also limited by material viscosities, thus requiring many passes over the surface to achieve a thickness in the 0.125 -inch range. This results in high application costs and a negative impact on the environment. Until recently, requirements for a 100 percent solid sprayable, environmentally friendly, lightweight thermal protection system that can be applied in a thick (greater than 0.125 inch) single-pass operation exceeded the capability of existing systems. Such coatings must be applied by hand lay-up techniques, especially for thermal and/or fire protection systems. The current formulation of these coatings has presented many problems such as worker safety, environmental hazards, waste, high cost, and application constraints. A system which can apply coatings without using hazardous materials would alleviate many of these problems. Potential applications include the aerospace thermal protective specialty coatings, chemical and petroleum industries that require fire-protection coatings that resist impact, chemicals, and weather. These markets can be penetrated by offering customized coatings applied by automated processes that are environmentally friendly. Author

SSME MAIN COMBUSTION CHAMBER (MCC) HOT OIL DEWAXING c27

Anthony U. Akpati *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 315-323 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

In an attempt to comply with the changing environmental regulations, a process was developed for the replacement of perchloroethylene in the dewaxing of the Space Shuttle Main Engine (SSME) Main Combustion Chamber (MCC) and other associated hardware filled with the Rigidax (R) casting compound. Rigidax (R) is a hard blue-dyed, calcium carbonate filled thermoplastic casting compound (melting point 77 C) that is melted and poured into hardware cavities to prevent contamination during material removal processes, i.e. machining, grinding, drilling, and deburring. Additionally, it serves as a maskant for designated areas during electroforming processes. Laboratory testing was conducted to evaluate seven alternate fluids for the replacement of perchloroethylene in the dewaxing process. Based upon successful laboratory results, a mineral oil was selected for testing on actual hardware. The final process developed involves simultaneous immersion and flushing of the MCC channels using a distinct eight stage process. A nonvolatile hydrocarbon analysis of a solvent flush sample is performed to determine the hardware cleanliness for comparison to the previous perchloroethylene dewaxing process. Author

BICARBONATE OF SODA PAINT STRIPPING PROCESS VALIDATION AND MATERIAL CHARACTERIZATION c27

Michael N. Haas *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 325-329 (For primary document see N95-31746 11-23)

Avail: CASI HC A01/MF A06

The Aircraft Production Division at San Antonio Air Logistics Center has conducted extensive investigation into the replacement of hazardous chemicals in aircraft component cleaning, degreasing, and depainting. One of the most viable solutions is process substitution utilizing abrasive techniques. SA-ALC has incorporated the use of Bicarbonate of Soda Blasting as one such substitution. Previous utilization of methylene chloride based chemical strippers and carbon removal agents has been replaced by a walk-in blast booth in which we remove carbon from engine nozzles and various gas turbine engine parts, depaint cowlings, and perform various other functions on a variety of parts. Prior to implementation of this new process, validation of the process was performed, and materials and waste stream characterization studies were conducted. These characterization studies examined the effects of the blasting process on the integrity of the thin-skinned aluminum substrates, the effects of the process on both air emissions and effluent disposal, and the effects on the personnel exposed to the process. WATERJET PROCESSES FOR COATING REMOVAL c27

Fletcher Burgess (United Space Boosters, Inc., Huntsville, AL.), Steve Cosby (United Space Boosters, Inc., Huntsville, AL.), and David Hoppe *In its* Aerospace Environmental Technology Conference Mar. 1995 p 331-336 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

USBI and NASA have been testing and investigating the use of high pressure water for coating removal for approximately the past 12 years at the Automated TPS (Thermal Protection System - ablative materials used for thermal protection during ascent and descent of the solid rocket boosters) Removal Facility located in the Productivity Enhancement Complex at Marshall Space Flight Center. Originally the task was to develop and automate the removal process and transfer the technology to a production facility at Kennedy Space Center. Since that time more and more applications and support roles for the waterjet technology have been realized. The facility has become a vital part of development activities ongoing at MSFC. It supports the development of environmentally compliant insulations, sealants, and coatings. It also supports bonding programs, test motors,

and pressure vessels. The most recent role of the cell is supporting Thiokol Corporation's solid rocket motor program in the development of waterjet degreasing and paint stripping methods. Currently vapor degreasing methods use 500,000 lbs. of ozone depleting chemicals per year. This paper describes the major cell equipment, test methods practiced, and coatings that have been removed. ULTRA-HIGH PRESSURE WATER JETTING FOR COATING REMOVAL AND SURFACE PREPARATION **c27**
Spencer T. Johnson *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 337-347 (For primary document see N95-31746 11-23)
Avail: CASI HC A03/MF A06

This paper shall examine the basics of water technology with particular attention paid to systems currently in use and some select new applications. By providing an overview of commercially available water jet systems in the context of recent case histories, potential users may evaluate the process for future applications. With the on going introduction of regulations prohibiting the use of chemical paint strippers, manual scrapping and dry abrasive media blasting, the need for an environmentally compliant coating removal process has been mandated. Water jet cleaning has been a traditional part of many industrial processed for year, although it has only been in the last few years that reliable pumping equipment capable of ultra-high pressure operation have become available. With the advent of water jet pumping equipment capable of sustaining pressures in excess of 36,000 psi. there has been shift away from lower pressure, high water volume systems. One of the major factors in driving industry to seek higher pressures is the ability to offer higher productivity rates while lowering the quantity of water used and subsequently reprocessed. Among benefits of the trend toward higher pressure/lower volume systems is the corresponding reduction in water jet reaction forces making hand held water jetting practical and safe. Other unique applications made possible by these new generation pumping systems include the use of alternative fluids including liquid ammonia for specialized and hazardous material removal applications. A review of the equipment used and the required modifications will be presented along with the conclusions reached reached during this test program. Author

The phase-out of CFC's and other ozone depleting chemicals has prompted industries to re-evaluate their present methods of cleaning. It has become necessary to find effective substitutes for their processes as well as to meet the new cleaning challenges of improved levels of cleanliness and to satisfy concerns about environmental impact of any alternative selected. One of the most popular alternatives being selected is aqueous cleaning. This method offers an alternative for removal of flux, grease/oil, buffing compound, particulates and other soils while minimizing environmental impact. What I will show are methods that can be employed in an aqueous cleaning system that will make it environmentally friendly, relatively simple to maintain and capable of yielding an even higher quality of cleanliness than previously obtained. I will also explore several drying techniques available for these systems and other alternatives along with recent improvements made in this technology. When considering any type of cleaning system, a number of variables should be determined before selecting the basic configuration. Some of these variables are: (1) Soil or contaminants being removed from your parts; (2) The level of cleanliness required; (3) The environmental considerations of your area; (4) Maintenance requirements; and (5) Operating costs. Historically, refurbishment processes for RSRM motor cases and components have employed environmentally harmful materials. Specifically, vapor degreasing processes consume and emit large amounts of ozone depleting compounds. This program evaluates the use of pressurized water cleaning systems as a replacement for the vapor degreasing process. Tests have been conducted to determine if high pressure water washing, without any form of additive cleaner, is a viable candidate for replacing vapor degreasing processes. This paper discusses the findings thus far of Engineering Test Plan - 1168 (ETP-1168), 'Evaluation of Pressurized Water Cleaning Systems for Hardware Refurbishment.' Author

Avail: CASI HC A03/MF A06

An advanced turbine/CO2 pellet accelerator is being evaluated as a depaint technology at Oak Ridge National Laboratory (ORNL). The program, sponsored by Warner Robins Air Logistics Center (ALC), Robins Air Force Base, Georgia, has developed a robot-compatible apparatus that efficiently accelerates pellets of dry ice with a high-speed rotating wheel. In comparison to the more conventional compressed air 'sandblast' pellet accelerators, the turbine system can achieve higher pellet speeds, has precise speed control, and is more than ten times as efficient. A preliminary study of the apparatus as a depaint technology has been undertaken. Depaint rates of military epoxy/urethane paint systems on 2024 and 7075 aluminum panels as a function of pellet speed and throughput have been measured. In addition, methods of enhancing the strip rate by combining infra-red heat lamps with pellet blasting and by combining the use of environmentally benign solvents with the pellet blasting have also been studied. The design and operation of the apparatus will be discussed along with data obtained from the depaint studies. Author

CO2 (DRY ICE) CLEANING SYSTEM **c37**
Donald M. Barnett *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference 391-398 (SEE N95-31746 11-23) Mar. 1995 (For primary document see N95-31746 11-23)
Avail: CASI HC A02/MF A06

Tomco Equipment Company has participated in the dry ice (solid carbon dioxide, CO2) cleaning industry for over ten years as a pioneer in the manufacturer of high density, dry ice cleaning pellet production equipment. For over four years Tomco high density pelletizers have been available to the dry ice cleaning industry. Approximately one year ago Tomco introduced the DI-250, a new dry ice blast unit making Tomco a single source supplier for sublimable media, particle blast, cleaning systems. This new blast unit is an all pneumatic, single discharge hose device. It meters the insertion of 1/8 inch diameter (or smaller), high density, dry ice pellets into a high pressure, propellant gas stream. The dry ice and propellant streams are controlled and mixed from the blast cabinet. From there the mixture is transported to the nozzle where the pellets are accelerated to an appropriate blasting velocity. When directed to impact upon a target area, these dry ice pellets have sufficient energy to effectively remove

most surface coatings through dry, abrasive contact. The meta-stable, dry ice pellets used for CO2 cleaning, while labeled 'high density,' are less dense than alternate, abrasive, particle blast media. In addition, after contacting the target surface, they return to their equilibrium condition: a superheated gas state. Most currently used grit blasting media are silicon dioxide based, which possess a sharp tetrahedral molecular structure. Silicon dioxide crystal structures will always produce smaller sharp-edged replicas of the original crystal upon fracture. Larger, softer dry ice pellets do not share the same sharp-edged crystalline structures as their non-sublimable counterparts when broken. In fact, upon contact with the target surface, dry ice pellets will plastically deform and break apart. As such, dry ice cleaning is less harmful to sensitive substrates, workers and the environment than chemical or abrasive cleaning systems. Dry ice cleaning system components include: a dry ice pellet supply, a non-reactive propellant gas source, a pellet and propellant metering device, and a media transport and acceleration hose and nozzle arrangement. Dry ice cleaning system operating parameters include: choice of propellant gas, its pressure and temperature, dry ice mass flow rate, dry ice pellet size and shape, and acceleration nozzle configuration. These parameters may be modified to fit different applications. The growth of the dry ice cleaning industry will depend upon timely data acquisition of the effects that independent changes in these parameters have on cleaning rates, with respect to different surface coating and substrate combinations. With this data, optimization of cleaning rates for particular applications will be possible. The analysis of the applicable range of modulation of these parameters, within system component mechanical constraints, has just begun. Author

A MICROWAVE PLASMA CLEANING APPARATUS **c75**

C. C. Tsai, W. D. Nelson, D. E. Schechter, L. M. Thompson, and A. L. Glover *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 399-408 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

In a microwave electron cyclotron resonance plasma source, reactive plasmas of oxygen and its mixtures of argon have been used for evaluating plasma cleaning technologies. Small aluminum samples (0.95 x 1.9 cm) were coated with thin films (less than or equal to 20 micrometers in thickness) of Shell Vitrea oil and cleaned with reactive plasmas. The discharge parameters, such as gas pressure, magnetic field, substrate biasing, and microwave power, were varied to change cleaning conditions. A mass spectroscopy (or residual gas analyzer) was used to monitor the status of plasma cleaning. Mass loss of the samples after plasma cleaning was measured to estimate cleaning rates. Measured cleaning rates of low-pressure (0.5-m torr) argon/oxygen plasmas were as high as 2.7 micrometers/min. X-ray photoelectron spectroscopy was used to determine cleanliness of the sample surfaces. In this paper, significant results of the plasma cleaning are reported and discussed. Author

AQUEOUS CLEANING AND VERIFICATION PROCESSES FOR PRECISION CLEANING OF SMALL PARTS **c37**

Gale J. Allen and Kenneth A. Fishell (Wiltech Corp. of Florida, Inc., Cocoa Beach, FL.) *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 411-419 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

The NASA Kennedy Space Center (KSC) Materials Science Laboratory (MSL) has developed a totally aqueous process for precision cleaning and verification of small components. In 1990 the Precision Cleaning Facility at KSC used approximately 228,000 kg (500,000 lbs) of chlorofluorocarbon (CFC) 113 in the cleaning operations. It is estimated that current CFC 113 usage has been reduced by 75 percent and it is projected that a 90 percent reduction will be achieved by the end of calendar year 1994. The cleaning process developed utilizes aqueous degreasers, aqueous surfactants, and ultrasonics in the cleaning operation and an aqueous surfactant, ultrasonics, and Total Organic Carbon Analyzer (TOCA) in the nonvolatile residue (NVR) and particulate analysis for verification of cleanliness. The cleaning and verification process is presented in its entirety, with comparison to the CFC 113 cleaning and verification process, including economic and labor costs/savings. Author

ULTRASONIC FREQUENCY SELECTION FOR AQUEOUS FINE CLEANING **c71**

Joann F. Becker *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 421-430 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

A study was conducted to evaluate ultrasonic cleaning systems for precision cleaning effectiveness for oxygen service hardware. This evaluation was specific for Rocketdyne Division of Rockwell Aerospace alloys and machining soils. Machining lubricants and hydraulic fluid were applied as soils to standardized complex test specimens designed to simulate typical hardware. The study consisted of tests which included 20, 25, 30, 40, 50, and 65 kHz ultrasonic cleaning systems. Two size categories of cleaning systems were evaluated, 3- to 10-gal laboratory size tanks and 35- to 320-gal industrial size tanks. The system properties of cavitation, frequency vs. cleaning effectiveness, the two types of transducers, and the power level of the system vs. size of the cleaning tank were investigated. The data obtained from this study was used to select the ultrasonic tanks for the aqueous fine clean facility installed at Rocketdyne. Author

QFD ANALYSIS OF RSRM AQUEOUS CLEANERS **c27**

Roy D. Marrs and Randy K. Jones *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 431-437 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

This paper presents a Quality Function Deployment (QFD) analysis of the final down-selected aqueous cleaners to be used on the Redesigned Solid Rocket Motor (RSRM) program. The new cleaner will replace solvent vapor degreasing. The RSRM Ozone Depleting Compound Elimination program is discontinuing the methyl chloroform vapor degreasing process and replacing it with a spray-in-air aqueous cleaning process. Previously, 15 cleaners were down-selected to two candidates by passing screening tests involving toxicity, flammability, cleaning efficiency, contaminant solubility, corrosion potential, cost, and bond strength. The two down-selected cleaners were further evaluated with more intensive testing and evaluated using QFD techniques to assess suitability for cleaning RSRM case and nozzle surfaces in preparation for adhesive bonding. A DESIGN OF EXPERIMENTS TEST TO DEFINE CRITICAL SPRAY CLEANING PARAMETERS FOR BRULIN 815 GD AND JETTACIN CLEANERS **c27**

Jill M. Keen (Thiokol Corp., Huntsville, AL.), Kurt B. Evans (Thiokol Corp., Brigham City, UT.), Robert L. Schiffman (Thiokol Corp., Brigham City, UT.), C. Darrell DeWeese, and Michael E. Prince *In its* Aerospace Environmental Technology Conference Mar. 1995 p 439-448 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

Experimental design testing was conducted to identify critical parameters of an aqueous spray process intended for cleaning solid rocket motor metal components (steel and aluminum). A two-level, six-parameter, fractional factorial matrix was constructed and conducted for two cleaners, Brulin 815 GD and Diversey Jettacin. The matrix parameters included cleaner temperature and concentration, wash density, wash pressure, rinse pressure, and dishwasher type. Other spray parameters: nozzle stand-off, rinse water temperature, wash and rinse time, dry conditions, and type of rinse water (deionized) were held constant. Matrix response testing utilized discriminating bond specimens (fracture energy and tensile adhesion strength) which represent critical production bond lines. Overall, Jettacin spray cleaning was insensitive to the range of conditions tested for all parameters and exhibited bond strengths significantly above the TCA test baseline for all bond lines tested. Brulin 815 was sensitive to cleaning temperature, but produced bond strengths above the TCA test baseline even at the lower temperatures. Ultimately, the experimental design database was utilized to recommend process parameter settings for future aqueous spray cleaning characterization work. Author

DEGRADATION OF TCE USING SEQUENTIAL ANAEROBIC BIOFILM AND AEROBIC IMMOBILIZED BED REACTOR **c37**

Kirit D. Chapatwala (Selma Univ., AL.), G. R. V. Babu (Selma Univ., AL.), Larry Baresi, and Richard M. Trunzo *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 449-457 (For primary document see N95-31746 11-23)

(Grant NAGw-3969)

Avail: CASI HC A02/MF A06

Bacteria capable of degrading trichloroethylene (TCE) were isolated from contaminated wastewaters and soil sites. The aerobic cultures were identified as Pseudomonas aeruginosa (four species) and Pseudomonas fluorescens. The optimal conditions for the growth of aerobic cultures were determined. The minimal inhibitory concentration values of TCE for Pseudomonas sps. were also determined. The aerobic cells were immobilized in calcium alginate in the form of beads. Degradation of TCE by the anaerobic and dichloroethylene (DCE) by aerobic cultures was studied using dual reactors - anaerobic biofilm and aerobic immobilized bed reactor. The minimal mineral salt (MMS) medium saturated with TCE was pumped at the rate of 1 ml per hour into the anaerobic reactor. The MMS medium saturated with DCE and supplemented with xylenes and toluene (3 ppm each) was pumped at the rate of 1 ml per hour into the fluidized air-uplift-type reactor containing the immobilized aerobic cells. The concentrations of TCE and DCE and the metabolites formed during their degradation by the anaerobic and aerobic cultures were monitored by GC. The preliminary study suggests that the anaerobic and aerobic cultures of our isolates can degrade TCE and DCE. Author

CLEANING WITHOUT CHLORINATED SOLVENTS **c27**

L. M. Thompson and R. F. Simandl *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 461-470 (For primary document see N95-31746 11-23)

(Contract DE-AC05-84OR-21400)

Avail: CASI HC A02/MF A06

Because of health and environmental concerns, many regulations have been passed in recent years regarding the use of chlorinated solvents. The Oak Ridge Y-12 Plant has had an active program to find alternatives for these solvents used in cleaning applications for the past 7 years. During this time frame, the quantity of solvents purchased has been reduced by 92 percent. The program has been a twofold effort. Vapor degreasers used in batch cleaning operations have been replaced by ultrasonic cleaning with aqueous detergent, and other organic solvents have been identified for use in hand-wiping or specialty operations. In order to qualify these alternatives for use, experimentation was conducted on cleaning ability as well as effects on subsequent operations such as welding, painting, and bonding. Cleaning ability was determined using techniques such as x-ray photoelectron spectroscopy (XPS) and Fourier transform infrared spectroscopy (FTIR) which are capable of examining monolayer levels of contamination on a surface. Solvents have been identified for removal of rust preventative oils, lapping oils, machining coolants, lubricants, greases, and mold releases. Solvents have also been evaluated for cleaning urethane foam spray guns, swelling of urethanes, and swelling of epoxies. Author

Avail: CASI HC A02/MF A06

HD-2 grease is deliberately applied to Shuttle Redesigned Solid Rocket Motor (RSRM) D6AC steel hardware parts as a temporary protective coating for storage and shipping. This HD-2 grease is the most common form of surface contamination on RSRM hardware and must be removed prior to subsequent surface treatment. Failure to achieve an acceptable level of cleanliness (HD-2 calcium grease removal) is a common cause of defect incidence. Common failures from ineffective cleaning include poor adhesion of surface coatings, reduced bond performance of structural adhesives, and failure to pass cleanliness inspection standards. The RSRM hardware is currently cleaned and refurbished using methyl chloroform (1,1,1-trichloroethane). This chlorinated solvent is mandated for elimination due to its ozone depleting characteristics. This report describes an experimental study of an aqueous cleaning system (which uses Brulin 815 GD) as a replacement for methyl chloroform. Evaluation of process control parameters for this cleaner are discussed as well as cleaning mechanisms for a spray-in-air process. Author

ENVIRONMENTALLY COMPATIBLE HAND WIPE CLEANING SOLVENTS **c27**

Catherine P. Clayton and Michael P. Kovach *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 491-497 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

Several solvents of environmental concern have previously been used for hand wipe cleaning of SRB surfaces, including 1,1,1-trichloroethane, perchloroethylene, toluene, xylene, and MEK. USBI determined the major types of surfaces involved, and qualification requirements of replacement cleaning agents. Nineteen environmentally compatible candidates were tested on 33 material substrates with 26 types of potential surface contaminants, involving over 7,000 individual evaluations. In addition to the cleaning performance evaluation, bonding, compatibility, and corrosion tests were conducted. Results showed that one cleaner was not optimum for all surfaces. In most instances, some of the candidates cleaned better than the 1,1,1-trichloroethane baseline control. Aqueous cleaners generally cleaned better, and were more compatible with nonmetallic materials, such as paints, plastics, and elastomers. Organic base cleaners were better on metal surfaces. Five cleaners have been qualified and are now being implemented in SRB hand wipe cleaning operations. Author

SURFACE CONTAMINATION ANALYSIS TECHNOLOGY TEAM OVERVIEW c25

H. DeWitt Burns *In its* Aerospace Environmental Technology Conference Mar. 1995 p 509-515 (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

A team was established which consisted of representatives from NASA (Marshall Space Flight Center and Langley Research Center), Thiokol Corporation, the University of Alabama in Huntsville, AC Engineering, SAIC, Martin Marietta, and Aerojet. The team's purpose was to bring together the appropriate personnel to determine what surface inspection techniques were applicable to multiprogram bonding surface cleanliness inspection. In order to identify appropriate techniques and their sensitivity to various contaminant families, calibration standards were developed. Producing standards included development of consistent low level contamination application techniques. Oxidation was also considered for effect on inspection equipment response. Ellipsometry was used for oxidation characterization. Verification testing was then accomplished to show that selected inspection techniques could detect subject contaminants at levels found to be detrimental to critical bond systems of interest. Once feasibility of identified techniques was shown, selected techniques and instrumentation could then be incorporated into a multipurpose inspection head and integrated with a robot for critical surface inspection. Inspection techniques currently being evaluated include optically stimulated electron emission (OSEE); near infrared (NIR) spectroscopy utilizing fiber optics; Fourier transform infrared (FTIR) spectroscopy; and ultraviolet (UV) fluorescence. Current plans are to demonstrate an integrated system in MSFC's Productivity Enhancement Complex within five years from initiation of this effort in 1992 assuming appropriate funding levels are maintained. This paper gives an overview of work accomplished by the team and future plans. Author

Corrosion products, oils and greases can potentially degrade material bonding properties. The Marshall Space Flight Center (MSFC) Surface Contamination Analysis Team (SCAT) utilizes a variety of analytical equipment to detect identify and quantify contamination on metallic and non-metallic substrates. Analysis techniques include FT-IR Microscopy (FT-IR), Near Infrared Optical Fiber Spectrometry (NIR), Optically Stimulated Electron Emission (OSEE), Ultraviolet Fluorescence (UVF) and Ellipsometry. To insure that consistent qualitative and quantitative information are obtained, standards are required to develop analysis techniques, to establish instrument sensitivity to potential contaminants, and to develop calibration curves. This paper describes techniques for preparing and preserving contamination standards. Calibration of surface contamination analysis systems is discussed, and methods are presented for evaluating the effects of potential contaminants on bonding properties. Author

The measurement and control of cleanliness for critical surfaces during manufacturing and in service provides a unique challenge for fulfillment of environmentally benign operations. Of particular interest has been work performed in maintaining quality in the production of bondline surfaces in propulsion systems and the identification of possible contaminants. This work requires an in-depth study of the possible sources of contamination, methodologies to identify contaminants, discrimination between contaminants and chemical species caused by environment, and the effect of particular contaminants on the bondline integrity of the critical surfaces. This presentation will provide an introduction to the use of optical fiber spectrometry in a nondestructive measurement system for process monitoring and how it can be used to help clarify issues concerning surface chemistry. Correlation of the Near Infrared (NIR) spectroscopic results with Optical Stimulated Electron Emission (OSEE) and ellipsometry will also be presented. Author

CONTAMINATION DETECTION NDE FOR CLEANING PROCESS INSPECTION c38

W. J. Marinelli, V. DiCristina, D. Sonnenfroh, and D. Blair *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 551-560 Sponsored by NASA. Langley Research Center (For primary document see N95-31746 11-23)

Avail: CASI HC A02/MF A06

In the joining of multilayer materials, and in welding, the cleanliness of the joining surface may play a large role in the quality of the resulting bond. No non-intrusive techniques are currently available for the rapid measurement of contamination on large or irregularly shaped structures prior to the joining process. An innovative technique for the measurement of contaminant levels in these structures using laser based imaging is

presented. The approach uses an ultraviolet excimer laser to illuminate large and/or irregular surface areas. The UV light induces fluorescence and is scattered from the contaminants. The illuminated area is viewed by an image-intensified CCD (charge coupled device) camera interfaced to a PC-based computer. The camera measures the fluorescence and/or scattering from the contaminants for comparison with established standards. Single shot measurements of contamination levels are possible. Hence, the technique may be used for on-line NDE testing during manufacturing processes. Author

Avail: CASI HC A02/MF A06

The use of reflectance Fourier transform infrared (FTIR) spectroscopy as a tool for surface inspection is described. Laboratory instruments and portable instruments can support remote sensing probes that can map chemical contaminants on surfaces with detection limits under the best of conditions in the sub-nanometer range, i.e.. near absolute cleanliness, excellent performance in the sub-micrometer range, and useful performance for films tens of microns thick. Examples of discovering and quantifying contamination such as mineral oils and greases, vegetable oils, and silicone oils on aluminum foil, galvanized sheet steel, smooth aluminum tubing, and sandblasted 7075 aluminum alloy and D6AC steel. The ability to map in time and space the distribution of oil stains on metals is demonstrated. Techniques associated with quantitatively applying oils to metals, subsequently verifying the application, and non-linear relationships between reflectance and the quantity oil are described. Author

Avail: CASI HC A02/MF A06

Contamination on bonding surfaces has been determined to be a primary cause for degraded bond strength in certain solid rocket motor bondlines. Hydrocarbon and silicone based organic contaminants that are airborne or directly introduced to a surface are a significant source of contamination. Diffuse infrared (IR) reflectance has historically been used as an effective technique for detection of organic contaminants, however, common laboratory methods involving the use of a Fourier transform IR spectrometer (FTIR) are impractical for inspecting the large bonding surface areas found on solid rocket motors. Optical methods involving the use of acousto-optic tunable filters and fixed bandpass optical filters are recommended for increased data acquisition speed. Testing and signal analysis methods are presented which provide for simultaneous measurement of contamination concentration and roughness level on rough metal surfaces contaminated with hydrocarbons. This paper will discuss how the Kennedy Space Center intends to perform precision cleaning verification by Air/Water Impingement in lieu of chlorofluorocarbon-113 gravimetric nonvolatile residue analysis (NVR). Test results will be given that demonstrate the effectiveness of the Air/Water system. A brief discussion of the Total Carbon method via the use of a high temperature combustion analyzer will also be given. The necessary equipment for impingement will be shown along with other possible applications of this technology. Author

Oxidizer propellant systems for liquid-fueled rocket engines must meet stringent cleanliness requirements for particulate and nonvolatile residue. These requirements were established to limit residual contaminants which could block small orifices or ignite in the oxidizer system during engine operation. Limiting organic residues in high pressure oxygen systems is particularly important. The current method of cleanliness verification used by Rocketdyne requires an organic solvent flush of the critical hardware surfaces. The solvent is filtered and analyzed for particulate matter, followed by gravimetric determination of the nonvolatile residue (NVR) content of the filtered solvent. The organic solvents currently specified for use (1,1,1-trichloroethane and CFC-113) are ozone-depleting chemicals slated for elimination by December 1995. A test program is in progress to evaluate alternative methods for cleanliness verification that do not require the use of ozone-depleting chemicals and that minimize or eliminate the use of solvents regulated as hazardous air pollutants or smog precursors. Initial results from the laboratory test program to evaluate aqueous-based methods and organic solvent flush methods for NVR verification are provided and compared with results obtained using the current method. Evaluation of the alternative methods was conducted using a range of contaminants encountered in the manufacture of rocket engine hardware. Author

VERIFICATION OF SURFACE PREPARATION FOR ADHESIVE BONDING **c25**
Rodney S. Myers *In* NASA. Marshall Space Flight Center, Aerospace Environmental Technology Conference Mar. 1995 p 603-612 (For primary document see N95-31746 11-23)
Avail: CASI HC A02/MF A06

A survey of solid rocket booster (SRB) production operations identified potential contaminants which might adversely affect bonding operations. Lap shear tests quantified these contaminants' effects on adhesive strength. The most potent contaminants were selected for additional studies on SRB thermal protection system (TPS) bonding processes.. Test panels were prepared with predetermined levels of contamination, visually inspected using white and black light, then bonded with three different TPS materials over the unremoved contamination. Bond test data showed that white and black light inspections are adequate inspection methods for TPS bonding operations. Extreme levels of contamination (higher than expected on flight hardware) had an insignificant effect on TPS bond strengths because of the apparent insensitivity of the adhesive system to contamination effects, and the comparatively weak cohesive strength of the TPS materials.

Spectroscopic ellipsometry is demonstrated to be extremely sensitive to contamination layers in the thickness range from 0.1 nm to 10 microns. In the present experiments we deposit either a thin lubricating oil (WD-40) or mineral oil continuously onto Ir, Cu, Al, Au, and V substrates from a bubbler, and monitor its thickness growth from sub-nanometer to tens of nanometers as a function of time. Re-evaporation of contaminant oils is also monitored in real-time by ellipsometry. Author

Avail: CASI HC A03/MF A06

The role of surface-sensitive chemical analysis (ESCA, AES, and SIMS) in a study to select a process to replace 1, 1, 1-trichloroethane (TCA) vapor degreasing as a steel and aluminum bonding surface preparation method is described. The effort was primarily concerned with spray-in-air cleaning processes involving aqueous alkaline and semi-aqueous cleaners and a contamination sensitive epoxy-to-metal bondline. While all five cleaners tested produced bonding strength results equal to or better than those produced by vapor degreasing, the aqueous alkaline cleaners yielded results which were superior to those produced by the semi-aqueous cleaners. The main reason for the enhanced performance appears to be a silicate layer left behind by the aqueous alkaline cleaners. The silicate layer increases the polarity of the surface and enhances epoxy-to-metal bonding. On the other hand, one of the semi-aqueous cleaners left a nonpolar carbonaceous residue which appeared to have a negative effect on epoxy-to-metal bonding. Differences in cleaning efficiency between cleaners/processes were also identified. These differences in surface chemistry, which were sufficient to affect bonding, were not detected by conventional chemical analysis techniques. Author

Increasing environmental legislation has brought about the development of many new environmental databases and software application packages to aid in the quest for environmental compliance. These databases and software packages are useful tools and applicable to a wide range of environmental areas from atmospheric modeling to materials replacement technology. The great abundance of such products and services can be very overwhelming when trying to identify the tools which best meet specific needs. This paper will discuss the types of environmental databases and software packages available. This discussion will also encompass the affected environmental areas of concern, product capabilities, and hardware requirements for product utilization. Author

The elimination of CFC-containing cleaning solvents for oxygen systems has prompted the development of a number of alternative cleaning solvents that must now be evaluated not only for cleanability, but compatibility as well. NASA Handbook 8060.1(NHB 8060.1) establishes the requirements for evaluation, testing, and selection of materials for use in oxygen rich environments. Materials intended for use in space vehicles, specified test facilities, and ground support equipment must meet the requirements of this document. In addition to the requirements of NHB 8060.1 for oxygen service, alternative cleaning solvents must also be evaluated in other areas (such as corrosivity, non-metals compatibility, non-volatile residue contamination, etc.). This paper will discuss the testing requirements of NHB 8060.1 and present preliminary results from early screening tests performed at Marshall Space Flight Center's Materials Combustion Research Facility. During the past two years, the NASA Marshall Space Flight Center (MSFC) has studied means to improve the transfer of technology from a major federal lab to a significant portion of an industrial segment. In the past, technology transfers had taken place with individual firms, or small groups of firms. This method of 'customized' transfer is often time consuming and can reduce the effectiveness of a response. Thus, a method was achieved to develop a standardized package on replacement of Chlorofluorocarbons (CFC's) that could be sent out to a large number of firms with minimum follow-up. Author

INTERFACIAL STUDIES OF COATED FIBER REINFORCED GLASS-CERAMIC MATRIX COMPOSITES Final Report, 1 Nov. 1992 - 31 Oct. 1994
John Brennan, Steven Nutt (Brown Univ., Providence, RI.), and Ellen Sun (Brown Univ., Providence, RI.) 31 Dec. 1994 138 p
(Contract F49620-92-C-0001)
(AD-A290780; R94-970150-3; AFOSR-95-0074TR) Avail: CASI HC A07/MF A02

The objective of this program is to develop an understanding of the

relationships between the fiber, fiber coating or coatings, and the glass-ceramic matrix, that will lead to a composite system exhibiting high strength, high toughness, and good thermal and environmental stability to temperatures of 1200 C. To meet this objective, the chemistry and microstructure of the fiber/coating(s)/matrix interfacial region and how these influence the interfacial bonding, strength, and toughness of the particular composite system was investigated. During the course of this program, emphasis was placed on the determination of the high temperature mechanical properties of the BMAS matrix/SiC over BN coated Nicalon fiber composite system, and how these properties relate to changes that may occur in the matrix, fiber coatings, or Nicalon fiber chemistry and microstructure. Specifically, short time flexural, short time tensile, tensile creep, and tensile fatigue testing was conducted in air to temperatures of 1200 C, all on the same composite sample. Flexural creep was also performed on similar composite samples and compared to the tensile creep results. In addition, Si3N4 over SN and BN by itself were evaluated as fiber coatings in the BMAS matrix/Nicalon fiber composite system. The effect of long-time heat-treatments in oxidizing and non- oxidizing environments were conducted on composites with different interface chemistries. With the collaboration of Brown University, SEM (scanning electron microscopy) and TEM (tunneling electron microscopy) analyses of the composites after being subjected to the various stress and temperature conditions were conducted. From these studies, damage modes and microstructural and chemical changes that occurred as a result of these tests were determined. Results of these studies are presented. DTIC

DESIGN OF FIBRE REINFORCED COMPOSITE PANELS FOR AEROSPACE APPLICATIONS Ph.D. Thesis
P. G. vanBladel 31 Jan. 1995 150 p
(PB95-197851; ISBN-90-9007838-X) Avail: CASI HC A07/MF A02

This thesis is a contribution to the design of fiber composite panels, in particular for aerospace applications. As composite structures are increasingly used in practice, experience is also gained in manufacture, maintenance and repair. However, the preliminary design of these structures, where only the loading and general requirements on the structure are given while the actual form and layup have yet to be defined, has not received as much attention. This has prompted the research leading to this thesis. Two specific types of panels are chosen as subjects of the research: sandwich panels and corrugated panels. As part of this work two computer programs have been developed as software tools for the designer: SAPANO for sandwich panels and COPANO for corrugated panels. This thesis can be seen as the theoretical manual for the programs, while separate user's manuals are available to assist in their use. NTIS

FATIGUE CRACK GROWTH BEHAVIOR OF A TITANIUM MATRIX COMPOSITE UNDER THERMOMECHANICAL LOADING Ph.D. Thesis
Paul Andrew Blatt 1993 239 p
Avail: Univ. Microfilms Order No. DA9420785

The fatigue crack growth characteristics of a 4-ply, unidirectional, titanium matrix composite, SCS-6/Ti-6Al-2Sn-4Zr-Mo, subjected to thermomechanical loading was investigated. The majority of work conducted for this research project was of an experimental nature. A test frame was assembled to perform the fully-automated, computer-controlled thermomechanical fatigue crack growth tests. A series of isothermal, in-phase, and out-of-phase crack growth tests were run. The test temperatures ranged from 150 deg C to 538 deg C and the fastest thermal frequency was 0.0083 Hz. The baseline isothermal and TMF data suggested that the time-at-temperature and the maximum temperature experienced by the composite significantly influenced the fatigue crack growth rates. Isothermal conditions produced higher crack growth rates than either in-phase or out-of-phase conditions for equivalent mechanical frequencies. Fiber bridging during both the isothermal and TMF tests was limited to a region of approximately 2-3 fibers directly behind the advancing crack tip. A linear summation approach was developed to model the effect of isothermal and thermomechanical cycling on the crack growth rates of the SCS-6/Ti-6Al-2Sn-4Zr-2Mo composite. The total fatigue crack growth rate was decomposed into cycle-dependent and time-dependent components. The model was able to correlate all the baseline fatigue crack growth tests as well predict the fatigue crack growth rate of a test which began under isothermal conditions and ended under in-phase conditions.

VIBRATION-DAMPING STRUCTURAL COMPONENT Patent
David J. Barrett, inventor (to Navy) 29 Nov. 1994 6 p Filed 3 Mar. 1993
(AD-D017376; US-Patent-5,368,914; US-Patent-Appl-SN-025535; US-Patent-Class-428-201) Avail: US Patent and Trademark Office

An improvement to a vibration-damping structural component of the type having viscoelastic material sandwiched between two outer structural layers of stiffness material is disclosed. An inner layer of stiffness material having two predominant surfaces is positioned between the two outer structural layers of stiffness material and is fixed along an edge of one of the two pre-dominant surfaces to one of the two outer structural layers of stiffness material along a line thereon corresponding to a nodal line of vibration. The remainder of the two predominant surfaces is fixed to the viscoelastic material. During flexural vibrations, the inner layer displaces in-plane with respect to the inner surfaces of the outer layers, causing greater shearing in the viscoelastic material, and therefore causing greater vibration damping in the structural component. THERMOVISCOELASTIC BEHAVIOUR OF SOLIDS
A. D. Irving, T. Dewson, S. J. Watson, and L. J. Speet Dec. 1994 26 p Prepared in cooperation with Technische Univ., Delft, Netherlands, and Bristol Univ., England
(PB95-196226; RAL-94-124) Avail: Issuing Activity (National Technical Information Service (NTIS))

The thermoviscoelastic behavior of a composite material is represented as a mixed linear-nonlinear convolution form of the Onsager equations. A vector multidimensional Volterra functional series expansion is used to describe the thermoviscoelastic constitutive relationships. Linear and mixed linear-nonlinear moment hierarchy time series analyses are performed to investigate the nature of the thermoviscoelastic phenomena. A tractable set of simultaneous equations with well behaved coefficients can be generated by taking time series moments of a suitably truncated Volterra series expansion. This moment hierarchy is used to determine the dynamic and steady state thermoviscoelastic properties of the composite. Statistical analyses on out of sample predictions made using the estimated response functions demonstrate that the characterization provides a good description of the thermoviscoelastic process. The transport coefficients are estimated and used to determine the flux-force surfaces which characterizes the behavior of the composite. These surfaces illustrate that Curie's principle for combined thermodynamic phenomena does not hold for the thermoviscoelastic process. The thermoviscoelastic behavior of composite materials under fatigue loadings is weakly nonlinear. NTIS

(Contract DE-AC05-84OR-21400)
(DE95-009131; CONF-941144-104) Avail: CASI HC A03/MF A01

Metal nanocluster composites have attractive properties for applications in nonlinear optics. However, traditional fabrication techniques, using melt-glass substrates, are severely constrained by equilibrium thermodynamics and kinetics. This paper describes the fabrication of metal nanoclusters in both crystalline and glassy hosts by ion implantation and pulsed laser deposition. The size and size distribution of the metal nanoclusters can be modified by controlling substrate temperature during implantation, by subsequent thermal annealing, or by laser irradiation. The authors have characterized the optical response of the composites by absorption and third-order nonlinear-optical spectroscopies; electron and

scanning-probe microscopies have been used to benchmark the physical characteristics of the composites. The outlook for controlling the structure and nonlinear optical response properties of these nanophase materials appears increasingly promising. DOE

A THEORY FOR PREDICTING AND MINIMIZING THE EFFECTS OF MATRIX DEGRADATION ON THE THERMOMECHANICAL PROPERTIES OF GENERAL LAMINATES Ph.D. Thesis
Stephen C. Hill 1993 379 p
Avail: Univ. Microfilms Order No. DA9420328

The effects of matrix degradation on the properties of general composite laminates are investigated. The changes in matrix properties due to hygrothermal environment and the presence of microcracking are considered. The matrix-dominated properties of constituent laminate plies are affected by these changes. Laminates dependent on matrix behavior, such as those with coupling, will exhibit the largest variation due to these effects. Models are developed for the effects on ply properties. Hygrothermally-induced effects are modeled as variations in shear modulus. A model for microcracking is developed which considers variations in all ply properties due to microcracking. Both of these models are easily incorporated into laminate analyses based on classical laminated plate theory. A model for predicting the potential distributions of crack density through the laminate thickness for given applied loads is developed. This model is used to analyze laminate behavior. The effects of matrix property variation on laminate moduli and compliances are investigated with an emphasis on extension-shear coupling. Hybrid laminates are presented for which the variation of coupling due to hygrothermal and microcracking effects is reduced or eliminated. Overall variations in properties are reduced with these laminates. The effects of microcracking on laminate coefficients of thermal expansion are investigated. Laminates which are initially thermally isotropic and shear stable may lose these properties due to microcracking. The effects of crack closure on laminate behavior are discussed. As laminate loads (or thermal stresses) vary, ply cracks may be forced open or closed. It is assumed that plies with closed cracks can be treated as uncracked plies. The resulting properties for these laminates become functions of the applied load and may behave nonlinearly. In general, the behavior of laminates changes when cracking develops. For example, initially symmetric laminates will become unsymmetric under certain loading conditions. Except in special cases, cracked laminates must be treated as general laminates with no special symmetries. Dissert. Abstr.

THE EFFECT OF INTERFACE PROPERTIES ON NICKEL BASE ALLOY COMPOSITES Final Report
M. Groves, T. Grossman, M. Senemeier, and K. Wright Jul. 1995 89 p
(Contract NAS3-26501; RTOP 505-63-12)
(NASA-CR-198363; E-9769; NAS 1.26:198363) Avail: CASI HC A05/MF A01

This program was performed to assess the extent to which mechanical behavior models can predict the properties of sapphire fiber/nickel aluminide matrix composites and help guide their development by defining improved combinations of matrix and interface coating. The program consisted of four tasks: 1) selection of the matrices and interface coating constituents using a modeling-based approach; 2) fabrication of the selected materials; 3) testing and evaluation of the materials; and 4) evaluation of the behavior models to develop recommendations. Ni-50Al and Ni-20Al-30Fe (a/o) matrices were selected which gave brittle and ductile behavior, respectively, and an interface coating of PVD YSZ was selected which provided strong bonding to the sapphire fiber. Significant fiber damage and strength loss was observed in the composites which made straightforward comparison of properties with models difficult. Nevertheless, the models selected generally provided property predictions which agreed well with results when fiber degradation was incorporated. The presence of a strong interface bond was felt to be detrimental in the NiAl MMC system where low toughness and low strength were observed. Author

ULTRASONIC CHARACTERIZATION OF FIBER-MATRIX INTERPHASIAL PROPERTIES AND DAMAGE IN HIGH-TEMPERATURE COMPOSITES Ph.D. Thesis
Ya-Cherng Chu 1994 370 p
Avail: Univ. Microfilms Order No. DA9420938

This study addresses ultrasonic characterization of fiber-matrix interphasial properties and damage in high-temperature composites. To accomplish this, experimental techniques for measurements of ultrasonic phase velocities and methodology for calculation of composite elastic moduli from velocity data are first developed and applied to unidirectional ceramic and intermetallic matrix composites. It is shown that computational error in the composite moduli is comparable to experimental error in the velocity data. For cross-ply composites, a novel method for determination of lamina elastic moduli from measurements on a (0/90)(8) composite is developed and validated experimentally. Second, a method to determine the elastic moduli of interphasial layers in high-temperature composites from the measured composite moduli is developed and applied to characterization of 3-micron thick carbon interphasial layers in ceramic and intermetallic matrix composites. Third, the techniques developed are used for assessment of oxidation and fatigue damage in ceramic and metal matrix composites. It is shown that ultrasonic phase velocities are very sensitive to damage and can effectively quantify damage severity. Appropriate models are applied to describe the effect of damage on the measured ultrasonic data, and they show reasonable agreement with experiments. Dissert. Abstr.

RESPONSE OF MECHANICALLY FASTENED COMPOSITE JOINTS UNDER MULTIPLE BYPASS LOADS Ph.D. Thesis
Chang-Li Hung 1994 193 p
Avail: Univ. Microfilms Order No. DA9422093

An analytical and experimental investigation was performed to study the response of laminated composites containing a mechanical fastener. The mechanics and mechanisms of bearing damage in fiber-reinforced laminated composites were the primary focuses of the experimental study. A specially designed semi-circular notched specimen was proposed to characterize pin bearing damage in the experiments. Double shear-lap bolted joints were also tested to evaluate the effects of bolt clamping on the mechanisms of bearing damage and the response of the laminates. A progressive failure model was developed to predict the bearing damage in the laminates as well as to estimate the mechanical response of the joints. The model consists of two parts: stress analysis and failure analysis. Stresses and deformations in the laminates were calculated by a nonlinear finite element analysis based on a finite deformation theory. In the failure analysis, damage accumulation criteria were proposed to determine the type and the state of damage in composites as functions of the given stress state. In order to describe the progressive degradation of composites, constitutive relations for damaged laminates were developed. To facilitate the use of the model, a computer code designated as 'BJSTAT' was developed for predicting the response and the strengths of bolted composite joints under multiple bypass loads. Data obtained from the present investigation and existing literature were used to validate the model. Overall, the predictions agreed with the data very well. Utilizing the code, numerical simulations were also conducted to generate the strength envelope for a bolted composite joint under multi-axial bypass loads. The envelope can provide information on the strength as well as the failure type of the joint as functions of the bypass loads and, therefore, is extremely useful in the joint design. Dissert. Abstr.

CHARACTERIZATION AND PREDICTION OF POST-IMPACT FATIGUE DAMAGE IN STITCHED COMPOSITES Ph.D. Thesis

Darwin Gregory Moon 1993 322 p
Avail: Univ. Microfilms Order No. DA9419666

The post-impact fatigue response of stitched carbon/epoxy composite materials was characterized and modeled in this investigation. The five material configurations evaluated were composed of uni-woven AS4 graphite lamina arranged in a (45/0/ - 45/90)(sub 6s) preform. Four preforms were reinforced by a modified lock stitch process, and each material was fabricated with a specific stitch row spacing of either 1/4, 3/16, or 1/8 inches. An unstitched baseline laminate was the fifth configuration. A brittle resin system was used to consolidate three stitched and the unstitched preforms, while a toughened resin system was used in a second preform which was also stitched with 1/4-inch rows. Short-block compression and compression-after-impact tests were conducted on every material to establish their baseline performances. All the impacts were performed with a 10-lb drop-weight impacter with a 1/2-inch hemispherical tup set to deliver a uniform 1500-in.-lb/in. energy level. Impacted fatigue specimens were tested at a 4-Hz frequency with a tension-compression stress ratio of R = -5. Dye-enhanced radiographic techniques and extensometers were used to monitor both the post-impact condition and the fatigue damage propagation. Destructive sectioning and pyrolysis methods were also used to quantify the damage states. Statistical analysis of the undamaged compressive properties shows no strength penalty associated with the stitching process. However, stitching reinforcement is found to have statistically significant affects on the elastic moduli and ultimate compressive strains. Lower elastic moduli and higher compression strains are found in the stitched materials compared to the unstitched baseline. All the post-impact fatigue coupons display stable damage growth. While circular delaminations elongate into ellipses in the unstitched samples, the stitched materials develop narrow damage zones transverse to the loading direction. These narrow zones are characterized by extensive regions of transverse shear failure surfaces. Critical damage zone length is predicted using a point-stress failure criterion based on an open-hole stress distribution. The propagation of these narrow zones is empirically predicted with a non-dimensional parameter, P, which allows the post-impact fatigue data to be correlated with an exponential damage growth model. A VISCOELASTIC ANISOTROPIC WAVE PROPAGATION MODEL FOR COMPOSITE CURE EVALUATION Ph.D. Thesis
James E. Eder 1994 173 p
Avail: Univ. Microfilms Order No. DA9420297

Current composite processing methods rely heavily upon traditional temperature, pressure and vacuum sensors to provide process feedback to cure controllers. These sensors are not capable of directly measuring the composite's physical properties, and thus limit the feedback potential for this process. This thesis investigates the sensitivity of ultrasonic sensors for measuring physical changes exhibited by a curing composite, considering both anisotropy and viscoelasticity. A material model is proposed to predict the time-dependent mechanical properties of a curing composite. This effective moduli model combines the properties of a viscoelastic curing resin, whose properties are a function of cure time, with those of an elastic fiber, whose properties are assumed independent of cure time to produce the viscoelastic moduli of a curing composite. Using the predicted time-dependent material properties, two significant boundary value problems are formulated and solved to predict ultrasonic measurements which are sensitive to the expected changes encountered during cure. These problems are: the reflection and refraction of obliquely incident ultrasonic waves on the interface between an isotropic elastic half-space and a viscoelastic anisotropic half-space (half-space case), as well as reflection and refraction of obliquely incident ultrasonic waves on a viscoelastic anisotropic layer bounded by two identical elastic isotropic half-spaces (layer case). Finally, some experimental verifications are presented demonstrating the utility of the theoretical formulations for both the half-space and layer cases. Increased sensitivity to changes in a curing laminate using oblique incidence is demonstrated both theoretically and experimentally for the half-space case. The layer results demonstrate the ability of the theoretical formulation to adequately predict the time dependence of the reflection factors at several different incident angles and frequencies, provided the wavelength is large enough to neglect scattering from the fibers. Some possible ultrasonic measurements are evaluated for their utility to monitor composite curing, along with some practical considerations for implementation of this technology. Dissert. Abstr.

(AD-A292701) Avail: CASI HC A03/MF A01

We performed real-time, in-situ CL intensity measurements this quarter during the MBE growth of Cd(x)Zn(1-x)Se/ZnSe MQW structures in which we varied the barrier and/or well widths for a fixed Cd(x)Zn(1-x)Se composition (x=0.2). In each case we quantified the integrated intensity of the CL emission observed during the growth. For the MQW structures grown thus far, the most intense integrated CL emission was detected from a structure comprised of 200A thick ZnSe barriers and 50A thick Cd(0.2)Zn(0.8)Se quantum wells. The 200A ZnSe/50 A CdZnSe MQW structure also exhibited strong room temperature exciton emission when ex-situ photoluminescence (PL) was performed on the sample. The PL intensity was measured by Dr. Simmons' group. Consequently, it appears that real-time, in-situ CL monitoring could have interesting applications with regard to the design and production of MQW structures and we plan to continue working in this area. EFFECTS OF HYDROSTATIC PRESSURE ON THE MECHANICAL BEHAVIOR OF COMPOSITE MATERIALS Final Report, Mar. 1993 - Jan. 1994
Christopher P. Hoppel, Travis A. Bogetti, and John W. Gillespie, Jr. Apr. 1995 64 p
(AD-A293162; ARL-TR-727) Avail: CASI HC A04/MF A01

Hydrostatic pressure can cause significant changes in the mechanical properties of composite materials. A thorough understanding of these effects is essential for the effective design of composite structures for high-pressure applications. In this report, the literature on the effects of hydrostatic pressure on the mechanical behavior of composite materials is reviewed. This includes a general description of the effects of hydrostatic pressure on unreinforced polymers and a detailed critique of the experimental work that has been done on composite materials. The section on composites is divided into three parts: compressive, tensile, and shear testing. For each type of testing, the test materials and techniques and the physical and quantitative results are discussed. DTIC

CHARACTERIZATION OF COMPRESSIVE DAMAGE MECHANISMS IN CERAMIC AND POLYMERIC MATRIX COMPOSITE MATERIALS Final Report, Oct. 1993 - Feb. 1995
James Lankford, Jr. Feb. 1995 78 p
(Contract N00014-92-C-0093)
(AD-A293171; Rept-06-5035) Avail: CASI HC A05/MF A01

Experiments involving expansion of the dynamic strain rate capabilities of the split Hopkinson pressure bar were performed. Unusually high strain rate hardening was obtained for the compressive failure of silicon nitride, while for silicon carbide, failure followed a lower rate of hardening, crack kinetics criterion. The silicon nitride results were interpreted in terms of plastic deformation, which changed the mode of failure from that observed at low strain rates, and altered the strength-strain rate dependency, apparently through the influence of dislocation generation upon microcrack nucleation. Recent experiments involved the response of monolithic ceramics and fiber-reinforced ceramic matrix composites to dynamic loading under hydrostatic confinement. Curious results were obtained for monolithic ceramics, which appeared to derive from crack initiation/growth kinetics and the stability of confined microcrack ensembles. Composites under confinement were found to reflect both dilatational and shear aspects of damage development, which are primarily a function of the matrix phase, while the effect of the fibers was to alter the relative kinetics and, under certain circumstances, the sequence of events involved in the macroscale growth of damage through the eventual zone of failure. Considerable effort has been devoted to new approaches to capturing the critical events associated with compressive kink band nucleation and development in polymeric matrix, fiber reinforced composites. MODELING OF FIBER-REINFORCED COMPOSITES INCORPORATING DISTINCT INTERFACE PROPERTIES Ph.D. Thesis
David Robert Veazie 1993 250 p
Avail: Univ. Microfilms Order No. DA9415674

A framework has been established to characterize the effects of distinct interphases in the study of fiber reinforced composites. On the basis of this framework, a rigorous analysis has been carried out for the transverse loading, both tensile normal and simple shear, of a unidirectional fiber reinforced composite. It is assumed that such an interphase is due to interfacial damage or is created deliberately by coating the fibers. By the use of the finite element method, a numerical analysis for a basic cell provides results for the micromechanical fields of stress and the micromechanical properties, with and without partial interphase failure. An analytical model is also developed to predict the macroscopic stress-strain behavior. The main objectives of this research are: (1) to develop micromechanics-based continuum models for transversely loaded fiber reinforced composites that incorporate distinct interphase properties; (2) to study the effects of distinct interphases on the local stress fields, the effective moduli, and along the matrix side of the interphase; and (3) to examine the effects of residual stresses on fiber composites with distinct interphases. The results of this work will enable the effect of interphase parameters on the overall elastic moduli to be determined prior to, as well as subsequent to, the development of interphase failure. INTERMODULATION INTERFERENCE (IMI) TESTING OF COMPOSITE MATERIALS Final Report
J. W. Rockway, J. C. Logan, J. H. Schukantz, and T. A. Danielson Sep. 1994 16 p
(AD-A288621; NRAD-TD-2705) Avail: CASI HC A03/MF A01

With the possibility of the large-scale use of graphite-bearing composites for topside structures and masts, some concern has been expressed as to whether these materials might be intermodulation interference (IMI) generators. To resolve this question, tests were performed to compare the relative signal levels of intermodulation generated by two graphite fiber composite material samples to a steel sample and to a brass sample. The graphite fiber composite material samples were representative of the materials that will be used in the Advanced Enclosed Mast/Sensor (AEM/S) System. The results of these tests were evaluated in terms of the potential of graphite-loaded composite structures to be significant generators of IMI on board Navy ships. ELASTIC AND INELASTIC MICROMECHANICAL ANALYSIS OF FUNCTIONALLY GRADED MATERIALS AND LAMINATED STRUCTURES USING TRANSFORMATION FIELDS Ph.D. Thesis
Joseph Robert Zuiker 1993 377 p
Avail: Univ. Microfilms Order No. DA9420377

Micromechanical analysis of composites generally considers a representative volume of the composite subjected to boundary conditions derived from constant stress or strain fields. Certain microstructures can not be accurately analyzed by such methods. These include cases of composite plate bending, and functionally graded composites in which severe gradients in local reinforcement volume fraction may affect the effective properties. In this thesis, the problem of a representative volume element (RVE) of the composite medium subjected to boundary conditions derived from linearly varying stress or strain fields is considered. Constraints on the form of the applied field are identified which produce simple solutions throughout the RVE. Constitutive relations are derived which relate stress and strain averages as well as stress and strain gradients in the RVE. Existing micromechanical techniques, including the Mori-Tanaka method, are extended to generate estimates of these new stiffness matrices. This extended Mori-Tanaka formulation is used to estimate effective stiffness and thermal expansion of statistically homogeneous composites. The results reduce to the standard Mori-Tanaka solutions under appropriate conditions. Deviations from standard Mori-Tanaka estimates exist for certain microstructures and are in agreement with experimental results. Further generalizations are incorporated in order to consider severe reinforcement volume fraction gradients. Results indicate differences of as much as 25 percent in the effective properties for extreme cases when reinforcement volume fraction gradient effects are considered. While the above results

are useful in the elastic analysis of composites, transformation field analysis methods have certain advantages over other techniques in the inelastic analysis of composites. In this thesis, the fundamental concepts of transformation field analysis are extended to the case of boundary conditions derived from linearly varying stress or strain for cases in which the boundary conditions and applied transformation fields satisfy certain equilibrium constraints. A simplified form of the generalized relations is used within the assumptions of classical laminated plate theory to obtain closed form estimates of all required concentration factors. Further refinement of the method has the potential for efficient accurate plate analysis algorithms.

The objectives of this ONR sponsored University Research Initiative (URI) entitled 'Materials for Adaptive Structural Acoustic Control' concern both basic fundamental studies and highly applied development of the piezoelectric and electrostrictive ferroelectric ceramics which carry both the sensing and actuation functions for adaptive control. The report documents work over the third year of this five year program. For convenience and continuity, the activities are grouped under the headings General Summary Papers, Materials Studies, Composite Sensors, Actuator Studies, Integration Issues, Processing Studies, Thin Film Ferroelectrics, and the Abstracts of graduating students on the program. The first general papers illustrate the educational role undertaken by MRL faculty both in the basic understanding of ferroics, and in the philosophy of their application in 'smart' systems. It is interesting that through work pioneered on earlier ONR programs in MRL, it is now possible to measure both direct and converse electrostrictive response in simple solids, and to thus explore models to explain the signs and magnitudes of these striction constants. The relaxor ferroelectrics have been a topic of study for more than 30 years in the laboratory, but recent breakthroughs have revolutionized the level of understanding and opened a vista for further potential application of size (scale) effects in ferroics. Electrical control of shape memory has been achieved in a number of electro-ferroic solids, but full exploitation will need more complete understanding of both ferroelectric and ferroelastic:ferroelectric domain wall processes. Using the planar-doping technique, Si has been shown to be amphoteric on (311)A InAlAs/InGaAs/InP grown by molecular beam epitaxy and excellent modulation-doped field effect transistors have been demonstrated. Through the use of an AlN/GaN strained superlattice buffer layer, high quality GaN layers were obtained. Crystalline SiC thin layers have been grown on 125 mm silicon-on-insulator (SOI) substrates. These two techniques have also been combined to synthesize the first GaN on SiC on SOI structure. Normal incidence infrared photodetectors using intersubband transitions in GaSb L-valley quantum wells have been demonstrated. Enhancement of normal incidence intervalence subband absorption in GaSb quantum wells coupled to a neighboring InAs has been observed. DTIC

MICROSTRUCTURE AND AGING RESPONSE OF SiCp REINFORCED A356 Al METAL MATRIX COMPOSITE SUBJECT TO POST FABRICATION THERMOMECHANICAL PROCESSING M.S. Thesis
Donald V. Avenger Dec. 1994 45 p
(AD-A292975) Avail: CASI HC A03/MF A01

The microstructure and aging behavior of a centrifugally cast A356 Al-SiCp metal matrix composite was studied as a function of post-fabrication processing via transmission electron microscopy (TEM) and differential scanning caloritemetry (DSO). The effects of total rolling strain, strain per rolling pass and rolling temperature on both microstructure and precipitation behavior were investigated. It was found that post fabrication processing had relatively little effect on the kinetics of the various precipitation processes that constitute aging, although they affected the amounts of the various precipitates significantly. IN SITU COMPOSITES IN THE ALUMINUM NITRIDE-ALUMINA SYSTEM Final Report, 19 Sep. 1994 - 19 Apr. 1995
Ender Savron Apr. 1995 33 p
(Contract N00014-94-C-0263)
(AD-A293776; QUEST-TR-650) Avail: CASI HC A03/MF A01

An attempt was made to produce in situ composites in an aluminum nitride-alumina system via pressureless reaction sintering. Different aluminum nitride-alumina compositions were prepared and fired at temperatures between 1900 C and 2200 C. Phase compositions were determined by x-ray diffraction, and microstructure development was evaluated by scanning electron microscopy. Elongated grains in an equiaxed matrix were achieved. However, the expected improvement in mechanical properties was offset by excessive grain growth and porosity. The high mobility of grain boundaries causes abnormal growth and pore entrapment without full densification. Suggestions for further work are offered to remedy the problems. DTIC

AN INVERSE METHOD TO MEASURE THE AXIAL MODULUS OF COMPOSITE MATERIALS UNDER TENSION Final Report
Andrew J. Hull 3 Jan. 1995 22 p
(AD-A293042; NUWC-NPt-TR-10801) Avail: CASI HC A03/MF A01

An inverse method is developed to measure the axial modulus of materials subjected to tensile loads. The approach is intended for use on long composite structures whose modulus is frequency dependent. The governing differential equations of a laboratory test configuration are solved and then inverted at three locations that correspond to sensor transfer functions. These three equations are next combined in such a way that the complex-valued axial modulus is equal to a function of the measured data and the known system parameters. This expression is a closed-form measurement of the modulus at each test frequency. An experiment is included to validate the method. Comparisons between the transfer function data and the model expressed with the measured modulus are in close agreement. DTIC

FINITE ELEMENT ANALYSIS OF DAMPED VIBRATIONS OF LAMINATED COMPOSITE PLATES Ph.D. Thesis
Baogang Hu 1993 190 p
(ISBN-0-315-84928-2) Avail: Univ. Microfilms Order No. DANN84928

In this thesis, the damped free vibrations of composites are treated from the viewpoint of macromechanical analysis. Two damping models are developed, namely: the viscoelastic damping (VED) model and the specific damping capacity (SDC) model. The important symmetry property of the damping matrix is retained in both models. A modified modal strain energy method is proposed for the evaluation of modal damping in the VED model using a real, instead of a complex, eigenvalue problem solution. Numerical studies of multi-degree-of-freedom systems are conducted to illustrate the better accuracy of the method compared to the modal strain energy method. The experimental data reported in the literature for damped free vibrations, in both polymer-matrix and metal-matrix composites, were used in the finite element analysis to test and compare the damping models. The natural frequencies and modal damping were obtained using both the VED and the SDC models. It was shown that the results from both models are in satisfactory agreement with the experimental data. Both models were found to be reasonably accurate for systems with low damping. Parametric studies were conducted to study the effects on damping of the side-to-thickness ratio, the principal moduli ratio, the total number of layers, the ply-angle, and boundary conditions. (NAL-TR-1254) Avail: CASI HC A03/MF A01

The objective of this study is to evaluate the material properties and laminate strength of a T800H/PMR-15 carbon/polyimide composite, which is selected as a candidate material for the primary structures of the unmanned small space vehicle HOPE (H-II Orbiting Plane). Various static tests were conducted to obtain data on the material properties and the laminate strengths for the unnotched and circular-holenotched specimens of a quasi-isotropic laminate. These tests were conducted at room temperature and a high temperature (300 C). The material property data include tension, compression, and short beam shear strengths, failure strain, elastic modulus, and Poisson's ratio. The first ply failure and the last ply failure strengths of the unnotched laminate are computed using the material property data obtained and the maximum stress and Tsai-Wu failure criteria. The strength of the laminate with a circular hole is predicted on the basis of the point stress and the average stress criteria. These analytical results are compared with the test results and discussed. Author

PROCESSING AND MICROSTRUCTURAL EVOLUTION OF ALUMINA/ALUMINUM ALLOY AND ALUMINUM NITRIDE/ALUMINUM ALLOY COMPOSITES BY DIRECTED MELT OXIDATION Ph.D. Thesis
Scott David Crudele 1994 251 p
Avail: Univ. Microfilms Order No. DA9423864

An experimental investigation on the directed oxidation of aluminum-zinc alloys to produce alumina/aluminum alloy composites with and without alumina preforms has been conducted. It has been suggested in the literature that Al-Mg alloys grow composites by the dissolution of a magnesia surface layer and reprecipitation of alumina in the composite. The intent of this investigation is to reveal relevant distinctions in the proposed dissolution-reprecipitation process as they apply to a more commercially interesting Zn containing alloy with a reinforcing preform. The TGA behavior and microstructural observations on the oxidation of Al-10Zn-8Si alloys were coupled with a thermodynamic and kinetic analysis to develop a composite growth model. Experiments were carried out in air at 1000-1200 C. At the higher temperatures (greater than 1100 C), Al2O3/Al composites grow by dissolving a ZnAl2O4 (spinel) surface layer. The dissolution process releases oxygen that reprecipitates in the form of Al2O3 on the existing composite, and also releases Zn and Al which migrate upward through the spinel to regenerate the surface oxide. Composite growth may only occur

when the surface regenerates at a rate comparable with that of the dissolution process. At the lower temperatures, 1000 C, the composite growth is limited by the spinel regeneration process, and becomes intermittent. The addition of Mg to this alloy allows normal composite growth by the dissolution of a surface (Zn,Mg)Al2O4 layer at the lower temperatures, 980-1060 C, but leads to heterogeneous microstructures with voids as the temperature increases above approximately 1060 C. The directed oxidation of an Al-Zn alloy into porous alumina preforms yields an Al2O3/Al composite matrix which fills the preform interstices. Al-10Zn-8Si-0.25Mg alloys that are oxidized from 960-1100 C, and Al-10Zn-8Si alloys that are oxidized at 800-1000 C climb up the preform particle. This climb process results in an extended oxidation front and voids in the composite. Elimination of Mg from the alloy suppresses climbing and void formation, but composite growth must be carried out at greater than or equal to 1100 C. An experimental investigation on the directed nitridation of aluminum-strontium alloys to produce aluminum nitride/aluminum alloy composites was also conducted with the intent of extending the directed oxidation knowledge to the nitridation process. Al-Sr-Si alloys exposed to N2 at 950-1200 C produce AlN/Al composites which can be partly explained by the dissolution of a strontium nitride surface layer. The lack of thermodynamic and kinetic information hinders the elaboration of the nitridation mechanism; although, it is clear that the basic principles to those operating in the directed oxidation process.

CONTROL OF INTERFACIAL CHEMISTRY AND MECHANICAL PROPERTIES IN METAL/CERAMIC COMPOSITES Ph.D. Thesis
Hsin-Fu Wang 1994 152 p
Avail: Univ. Microfilms Order No. DA9424341

Evaluation of the mechanical properties of metal/ceramic interfaces (Ti/Al2O3) was accomplished by using four-point bending tests, nanoindentation tests and fiber pushout tests. At first, the interfacial fracture energy of composites with different applied bonding temperatures from 700 C to 1000 C and thickness of the metal interlayers were measured by four-point bending tests. The mixed mode interfacial fracture energy of the Ti/Al2O3 interface was found to increase with increasing bonding temperatures up to 950 C. There is increasing interdiffusion of the constituent atoms across the interfaces with increasing temperature as verified by X-ray mapping. Thus, a stronger chemical bond forms between the Ti and the Al2O3. Above this temperature, the interfacial fracture energy drops due to the formation of a continuous brittle intermetallic compound (Ti3Al) at the Ti/Al2O3 interface. Modification of the interface was achieved with a diffusion barrier consisting of a refractory metal and Y2O3 duplex coating prepared by r.f. sputtering methods. The diffusion barrier significantly reduces the diffusion of the constituent atoms and prevents the formation of a continuous Ti3Al reaction layer, thus maintaining the chemical integrity and stability at the Ti/Al2O3 interface. The interfacial fracture energy can be further reduced by providing thinner Ti interlayers. The contribution of the energy dissipation process to the interfacial fracture energy is due to plastic energy absorption in the Ti interlayer during the fracture process. The interfacial shear strength, interfacial frictional stress and mode II interfacial fracture energy of the fiber composites were obtained by performing the fiber pushout tests. Using the Atomic Force Microscope (AFM), the surface roughness and texture of the three different Al2O3 fibers were evaluated. Incorporation of the experimental data and the theory gives the calculated frictional coefficient to be 0.35. The distribution of the frictional force on the refractory metal coated Al2O3 surfaces was also measured by the Lateral Force Microscope (LFM) with frictional coefficient ranging from 0.2 to 0.8, the average frictional coefficient being 0.38.

INFLUENCE OF FIBER CONTENT ON MECHANICAL PERFORMANCE OF SIC-FIBER-REINFORCED REACTION-BONDED SILICON NITRIDE COMPOSITES
D. Singh, J. P. Singh, and R. T. Bhatt Jan. 1995 14 p Presented at the 19th Annual Conference on Advanced Ceramics, Materials and Structures, Cocoa Beach, FL, 9-12 Jan. 1995 Prepared in cooperation with NASA. Lewis Research Center, Cleveland, OH
(Contract W-31-109-eng-38)
(NASA-TM-110639; NAS 1.15:110639; DE95-009903; ANL/ET/CP-83786; CONF-950129-5) Avail: CASI HC A03/MF A01

The effect of fiber content on the resulting mechanical properties (first matrix cracking stress, ultimate strength, and work-of-fracture) of silicon carbide (SiC)-fiber-reinforced reaction-bonded silicon nitride (RBSN) matrix composites was investigated. Flexure tests were used to evaluate mechanical properties of composites containing various fiber contents. The first matrix cracking stress, ultimate strength, and work-of-fracture of the composites increased with increasing fiber content, reaching a peak value at a fiber content of (approximately) 16 vol.%. Further increases in fiber content degraded the mechanical properties of the composites. The variations in mechanical properties with fiber contents were correlated to the residual stresses in the matrix phase, processing related flaws, and failure modes observed in these composites. FAILURE MECHANISMS IN COMPOSITE PLATES SUBJECTED TO IN-PLANE COMPRESSIVE LOADING Ph.D. Thesis
Amir Reza Khamseh 1994 157 p
Avail: Univ. Microfilms Order No. DA9423229

An experimental investigation into the failure mechanisms of composite plates in the presence of stress gradients, generated by circular cutouts, subjected to uniaxial/biaxial compressive loading was carried out. The focus of the study was identification and analysis of the failure initiation mechanisms in laminated plates as a function of the centrally located circular hole and loading parameters. The experimental investigation was divided into two parts, the first dealing with single axis loading and the second addressing biaxial loading. The materials under investigation were comprised of a set of specially designed single layer unidirectional composites, as well as a series of 48 layer graphite/epoxy specimens with varying stacking ply orientation, provided by NASA Langley. Test specimens containing plies oriented in the direction of loading subjected to uniaxial loading exhibited failure initiation along the edge of the hole, perpendicular to the fiber and loading direction, traversing into the specimen in the form of fiber kinking, followed by delamination (i.e. several of the specimens exhibited fiber kinking failure with no evidence of delamination, or delamination growth lagging behind the kink tip). The above mentioned specimens subjected to biaxial loading exhibited similar failure mechanisms as their uniaxial counterparts, but failure initiation was in the form of fiber-matrix debonding. Shear dominated specimens, which have fibers oriented at 45 deg angles to the loading direction, exhibited highly nonlinear strain to failure values with no indication of localized fiber failure. The failure mode for these type of composites was shear induced delamination caused by large wavelength in-plane fiber microbuckling. A computational approach was employed to simulate some of the uniaxial experimental results, through the use of of the finite element method. The finite element analysis software HKS-ABAQUS was used, taking into account material nonlinearities. The computational analysis revealed the roles of fiber failure strain and hole gradient in the in-plane failure analysis of composite plates. This investigation has yielded results and shown trends in the failure patterns of composites and the results reported herein can be incorporated in developing their micromechanics based failure criteria. Dissert. Abstr.

CONTRIBUTIONS TO THE DESIGN OF NEUTRAL CUTOUTS IN LAMINATED PLATES AND SHELLS Ph.D. Thesis
Erol Senocak 1994 106 p
Avail: Univ. Microfilms Order No. DA9423314

The problem of designing a cutout and a suitable cutout edge reinforcement (termed neutral hole) in a load bearing structural member in the form of a plate or shell, such that the cut structure maintains its stress state with a minimal departure from the stress state of the uncut structure, is addressed. A particular class of structural optimization for laminated thin walled structures is considered, in which the geometry of the structure is obtained as a solution to a particular problem, for known states of stress, strain, boundary conditions, and appropriate constraints (sometimes called inverse problems in elasticity for some specific cases). In this category, either stress concentrations are reduced (optimized) by determining the shape of the openings (harmonic holes), or stress states in the cut structure with reinforcement are maintained unchanged compared to that of the uncut structure (neutral holes). Symmetrically laminated composite plates and circular cylindrical shells are considered. Planar loading

and pure bending cases for laminated plates, and hydrostatic pressure and axial compression loading cases for the shells are assumed. Unsymmetrically laminated plates are also studied and material coupling (bending-stretching coupling due to material elastic properties) has been investigated. Plates are analyzed using classical lamination theory, and the Donnell shallow thin shell model is applied to investigate laminated shells. An intermediate class of deformation theory, the von Karman model for plates, is considered for the unsymmetrically laminated plates. The reinforcement is modeled as a one-dimensional rod/beam type structural element. In the reinforcements that were considered, the fibers are tangential to the edge of the cutout. This is not a restriction, as the solution presented could very well accommodate other types of constitutive models as well. The shape of the cutout and the cross-sectional area of the reinforcement are determined in closed form. A novel approach is introduced for the determination of the optimum reinforcement when the analytical solution fails to produce a neutral condition. The original (uncut) stiffness of the plate and shell structures are restored by appropriately designing an edge reinforcement around the cutout. The buckling load of the designed shells are analyzed via the finite element method. It is shown that the resistance to buckling is almost completely recovered. An experimental investigation has been carried out to verify some of the results for the shell structures, and the results are presented. Dissert. Abstr.

A STUDY OF ELEVATED TEMPERATURE TESTING TECHNIQUES FOR THE FATIGUE BEHAVIOR OF PMCS: APPLICATION TO T650-35/AMB21

Andrew L. Gyekenyesi (Cleveland State Univ., OH.), Michael G. Gastelli (NYMA, Inc., Brook Park, OH.), John R. Ellis, and Christopher S. Burke (NYMA, Inc., Brook Park, OH.) Jul. 1995 22 p

(Contract NAS3-27186; RTOP 538-06-15)

(NASA-TM-106927; E-9648; NAS 1.15:106927) Avail: CASI HC A03/MF A01

An experimental study was conducted to investigate the mechanical behavior of a T650-35/AMB21 eight-harness satin weave polymer composite system. Emphasis was placed on the development and refinement of techniques used in elevated temperature uniaxial PMC testing. Issues such as specimen design, gripping, strain measurement, and temperature control and measurement were addressed. Quasi-static tensile and fatigue properties (R(sub sigma) = 0.1) were examined at room and elevated temperatures. Stiffness degradation and strain accumulation during fatigue cycling were recorded to monitor damage progression and provide insight for future analytical modeling efforts. Accomplishments included an untabbed dog-bone specimen design which consistently failed in the gage section, accurate temperature control and assessment, and continuous in-situ strain measurement capability during fatigue loading at elevated temperatures. Finally, strain accumulation and stiffness degradation during fatigue cycling appeared to be good indicators of damage progression. Author

THEORETICAL ABSORPTION SPECTROSCOPY OF HIGH-TEMPERATURE METAL VAPORS: MODEL AND EXPERIMENT COMPARED Final Report

Jeffrey D. Mills Dec. 1994 36 p

(AF Proj. 2308)

(AD-A290872; PL-TR-94-3001) Avail: CASI HC A03/MF A01

Theoretical calculations in support of absorption spectroscopy of buffered metallic vapors in the Plasma Spectroscopy Cell are described. After a brief exposition of the theoretical principles and ingredients of the quantum-mechanical, state-to-state treatment of transition processes in atoms and diatoms at thermodynamic equilibrium, various aspects of the model and experimental absorption spectra for the lithium system are compared and discussed. Special emphasis is given to outlining those spectral characteristics which are most relevant to the energy transfer properties of the sample but are as yet incompletely understood and to determining the minimal computational algorithm sufficient to rapidly and accurately calculate absorption by these materials. An account of the modelling of the aluminum/lithium system preparative to a search for a heretofore unobserved molecule, aluminum lithium, is also included. DTIC

STANDARDIZATION OF (13)CO2 PRODUCTION PROCEDURE FROM ORGANIC MATTER FOR MASS SPECTROMETRIC ANALYSIS

M. I. Sajjad, Z. Latif, M. A. Tasneem, M. Ali, and R. Bilal Nov. 1993 16 p

(DE95-614629; PINSTECH-RIAD-138) Avail: CASI HC A03/MF A01 (US Sales Only)

This report summarizes the ways and means by which (13)CO2 production procedure from organic matter can be standardized. Optimum sample preparation conditions were determined to get reproducible results. Plant combustion for six minutes at 900-1000 C with pure O2 and ten minutes for conversion of CO to CO2 over CUO gauze at 850 C have been found optimum conditions. Internal standards: PINSTECH wheat straw, PINSTECH grass sample, Glucose-D glaxo PINSTECH and polyethylene foil PINSTECH were selected, and calibrated against IAEA Sucrose and polyethylene foil standards. These internal standards have been used for correction of delta C-13 results. The mechanisms for the correction of results has been described. Causes of isotope fractionation of plant samples were determined. Statistical summary of measured results for delta C-13 standards has also been given. DOE

CATALYTIC REACTIONS OF SYNTHESIS GAS. PART 4: HETEROGENEOUS HYDROFORMYLATION

M. Niemelae 1994 28 p

(PB95-195558; ISBN-951-22-2369-4) Avail: CASI HC A03/MF A01

Rhodium and cobalt exhibit superior performance in homogeneous hydroformylation compared with other metal catalysts. Thus far heterogeneous hydroformylation catalysts have not been commercialized. Decomposed carbonyls on various inorganic supports have been studied in hydroformylation reaction as a probe reaction for the Fischer-Tropsch synthesis. Addition of ethylene and propylene to the reaction mixture of CO and H2 has resulted in the formation of typical hydroformylation products particularly on Rh and Co catalysts. In conclusion, ethylene or propylene hydroformylation is a suitable test reaction for molecular activation of CO, and it supplements well the catalyst characterizations by dissociative activation of CO in synthesis gas reaction. One major focus of the work during the report was the design, fabrication, and installation of the necessary apparatus to conduct an investigation of jet flames in a crossflow. A second focus was a parametric investigation of precessing jet flames in an unconfined, quiescent ambient. Parameters varied include nozzle diameter, jet deflection angle, initial jet velocity (Reynolds number), dimensionless precession frequency (Strouhal number), and fuel type. The overall objective of this study is to provide an increased understanding of the combined effects of fluid mechanics and chemical kinetics in the production and emission of oxides of nitrogen from gas-burning combustion systems. APPLICATION OF SPIN-SENSITIVE ELECTRON SPECTROSCOPIES TO INVESTIGATIONS OF ELECTRONIC AND MAGNETIC PROPERTIES OF SOLID SURFACES AND EPITAXIAL SYSTEMS Final Report, 1 Jan. 1986 - 31 Oct. 1994
G. K. Walters and F. B. Dunning Feb. 1995 13 p
(Contract DE-FG05-86ER-45233)
(DE95-010154; DOE/ER-45233/10) Avail: CASI HC A03/MF A01

The principal objectives of the research have been improved understanding and characterization of electronic and magnetic properties of surfaces, adsorbates, and epitaxially-grown systems. Toward this end, substantial effort has also been directed toward better elucidation of the dynamical processes involved in electron-surface and atom-surface interactions, since these provide the bases for electron spectroscopies commonly used for probing surface properties. To accomplish these objectives, three novel spin-sensitive electron spectroscopies have been developed in this laboratory, and these have been exploited to provide new information not accessible using the corresponding conventional (non-spin-sensitive) spectroscopies. These spectroscopies and the new knowledge that has resulted from their application are discussed briefly in the following three sections of the report: spin polarized low energy electron diffraction (SPLEED); spin polarized electron energy loss spectroscopy (SPEELS); and spin polarized (metastable atom) deexcitation spectroscopy (SPMDS). AN EXPERIMENTAL AND NUMERICAL STUDY ON THE STRUCTURE AND EXTINCTION OF LAMINAR PREMIXED FLAMES Ph.D. Thesis
Chao Fu Daniels 1994 202 p
Avail: Univ. Microfilms Order No. DA9425336

The laminar premixed flames are studied to obtain the flame speed and flame thickness under the influence of stretch and preferential diffusion. A new concept of flame thickness which is defined by velocity profile of the flame structure is used. The extinction mechanism for the flames with different preferential diffusion effect is also studied and the extinction criterion is established for the adiabatic flames under stretch. The laminar premixed flames are studied by both experimentation and numerical calculation. Experimentally, the counterflow configuration technique is applied to establish the adiabatic, planar twin flames. The velocity profiles for methane/air and propane/air flames with different equivalence ratios are measured by laser Doppler velocimetry to obtain the flame speed and flame thickness under different stretch and preferential diffusion conditions. The numerical calculations based on different chemical mechanisms for methane/air and propane/air flames are also carried out to obtain the flame speed, flame thickness, and detailed flame structure in terms of different stretch rates and Le numbers for comparison with the experimental results. The comparison between the new concept of flame thickness and the existing widely used flame thickness has shown that the new flame thickness defined by the velocity profile can be used as the definition of the flame thickness. Based on the experimentation and calculation results, the local flame speed and local flame thickness are used to analyze the extinction behavior of the flames. The local Karlovitz number is proposed based on the local flame speed and local flame thickness, which can truly represent the influence of the stretch on the flame. A new nondimensional KT number is formed based on the local Karlovitz number and a temperature term, where the temperature term is the ratio between the temperature difference for the combustion and the flame temperature. The extinction will occur when the KT number is about unity. Dissert. Abstr.

Recently, a new approach to multi-wavelength remote sensing has been proposed based on the generation and detection of spectral 'pickets' synthesized from the frequency filtered bandwidth of a modelocked laser. Using linear array liquid crystal spatial light modulator (SLM) technology for spectral filtering permits real time grey scale control of individual picket amplitudes and phases, making it possible to independently modulate picket characteristics in the kHz to MHz regime. Due to the versatility of this approach, a whole suite of spectroscopies based on detection techniques that are similar to conventional sideband spectroscopies can be implemented. These techniques not only inherit the S/N advantages of their conventional counterparts, they can also be easily extended to simultaneous multi-wavelength operation using frequency multiplex techniques and configured for real time adaptive data acquisition. We report the laboratory demonstration and theoretical development of a new class of zero background AM modulated spectroscopic probes for differential absorption measurements. Preliminary detection sensitivities on the order of 10(exp -6) can be inferred from our measurements. Application of this technique to realistic remote sensing scenarios, advantages over other modulation and direct detection approaches, as well as the present limitations and theoretical limits to detection sensitivity will be discussed. (Contract W-7405-eng-36)
(DE95-009417; LA-UR-95-966; CONF-950158-2) Avail: CASI HC A02/MF A01

This group has developed a process to extract metal ions from dilute aqueous solutions. The process uses water soluble polymers to complex metal ions. The metal/polymer complex is concentrated by ultrafiltration and the metals are recovered by a pH adjustment that frees the metal ions. The metal ions pass through the ultrafiltration membrane and are recovered in a concentrated form suitable for reuse. Surfactants are present in one of the target waste streams. Surfactants foul the costly ultrafiltration membranes. It was necessary to remove the surfactants before processing the waste stream. This paper discusses an on-line device the authors fabricated to monitor the process stream to assure that all the surfactant had been removed. The device is inexpensive and sensitive to very low levels of surfactants. DOE

Sea and Air, Houston, TX, 5-8 Jun. 1995
(DE95-008945; DOE/METC-C/95/7183; CONF-950629-2) Avail: CASI HC A03/MF A01

As part of the Department of Energy's Advanced Gas Turbine Systems Program, an investigation is being performed to evaluate 'pressure gain' combustion systems for gas turbine applications. This paper presents experimental pressure gain and pollutant emission data from such combustion systems. Numerical predictions for certain combustor geometries are also presented. It is reported that for suitable aerovalved pulse combustor geometries studied experimentally, an overall combustor pressure gain of nearly 1 percent can be achieved. It is also shown that for one combustion system operating under typical gas turbine conditions, NO(x) and CO emissions, are about 30 ppmv and 8 ppmv, respectively. DOE

(DE95-010177; DOE/ER-13829/T1) Avail: CASI HC A03/MF A01

During the catalytic oxidation of hydrocarbons over many metal oxides, radicals are formed on the surface and these intermediates emanate into the gas phase where they become involved in homogeneous reactions. Examples include methyl radicals formed during the oxidative coupling of methane, allyl radicals formed during the partial oxidation of propylene, and hydroxyl radicals formed during the reaction of water with molecular oxygen. Higher temperatures (greater than 600 C) generally favor radical formation. Other factors that effect radical formation, as well as secondary reactions of the radicals with surfaces, have been investigated. A matrix isolation electron spin resonance (MIESR) system and a laser-induced fluorescence (LIF) system have been used to study hydrocarbon and hydroxyl radicals, respectively. The goal of the research is to understand the role that these surface generated intermediates play in catalytic reactions, with emphasis on the partial and complete oxidation of hydrocarbons. The results will find application in the utilization of natural gas reserves in an efficient and nonpolluting manner. DOE

METAL NANOTUBULE MEMBRANES WITH ELECTROCHEMICALLY SWITCHABLE ION-TRANSPORT SELECTIVITY Interim Report
Matsuhiko Nishizawa, Vinod P. Menon, and Charles R. Martin Mar. 1995 20 p
(Contract N00014-82-K-0162)
(AD-A292712; TR-100) Avail: CASI HC A03/MF A01

Membranes that contain cylindrical metal nanotubules that span the complete thickness of the membrane are described. The inside radius of the nanotubules can be varied at will; nanotubule radii as small as 0.8 nm are reported here. These metal nanotubule membranes show selective ion transport analogous to that observed in ion-exchange polymers. Ion permselectivity is observed because excess charge density can be present on the inner walls of the metal tubules. The membranes reject ions of the same sign, and transport ions of the opposite sign, as this excess charge. Because the sign of the excess charge on the tubule can be changed potentiostatically, a metal nanotubule membrane can be either cation selective or anion selective, depending on the potential applied to the membrane. EXTENSION OF THE PORE TREE MODEL TO DESCRIBE PORE INTERCONNECTIVITY
Girard A. Simons 31 Oct. 1994 15 p
(Contract DAAH04-94-C-0075)
(AD-A290366; ARO-32900.2-GS-S) Avail: CASI HC A03/MF A01

The 'pore tree' model of pore structure (Simons and Finson, 1979; Simons, 1982) was developed for catalysts and sorbents to allow diffusion within a porous media in the absence of convection through the media. The pore tree model is extended herein to describe the permeable pore structure which characterizes the subsurface flow of water in soil, the dispersion of contaminants and the in-situ remediation of contaminated sites. Permeability requires a statistical determination of the 'branches' that are common to several trees to allow percolation through the large scale (mobile) structure in addition to diffusion through the smaller scale (immobile) structure. While permeability is dominated by the largest pores, it is important to determine the level of convection that is occurring at the intermediate scales in order to accurately describe transport. This and subcequent interim technical reports will be self contained in that each report will contain the previous report plus new work described in the last 34 pages of each report. DTIC

SPECIFIC RATE COEFFICIENTS FROM VIBRATIONAL OVERTONE ACTIVATION OF 1-METHYLCYCLOPROPENE
Deanne Snavely, Oleg Grinevich, Salah Hassoon, and Geoff Snavely 1 Dec. 1994 25 p
(Contract N00014-91-J-4130)
(AD-A288755; TR-16) Avail: CASI HC A03/MF A01

Laser vibrational overtone activation has been used to investigate the reaction channel competition in the isomerization of 1-methylcyclopropene (MCPene). The vibrational overtone activation of three types of CH stretches (methyl, methlenic and olefinic) in the 5v sub CH and 6v sub CH transitions was initiated and all three products (2-butyne, 1,3-butadiene and 1,2-butadiene) were detected by gas chromatography. Stern Volmer plots were constructed for the appearance of each individual product and the derived experimental specific rate coefficients were compared to those of RRKM theory. The rate coefficients at high energy were 10% higher than predicted and those at low energy were 60 to 80% high. Product ratios of 1,3-butadiene to 2-butyne were independent of pressure. These ratios were compared to the RRKM ratios. The product yield ratio for the lowest energy photolysis compared well with the RRKM ratio but the two higher energy product yield ratios were approximately 35% lower than the RRKM ratio. The implications of these comparisons are discussed. DTIC

AQUEOUS TIO2 PHOTOCATALYSIS OF METAL-EDTA COMPLEXES
Tom Madden, Abhaya K. Datye (New Mexico Univ., Albuquerque, NM.), Michael R. Prairie, and Bertha M. Stange 1995 10 p Presented at the 5th Annual Waste-management Education and Research Consortium (WERC) Technology Development Conference, Las Cruces, NM, 18-20 Apr. 1995
(Contract DE-AC04-94AL-85000)
(DE95-011058; SAND-95-0763C; CONF-9504135-2) Avail: CASI HC A02/MF A01

This report describes the results of experiments performed to determine the viability of titanium dioxide photocatalysis towards the treatment of water contaminated with different metal-EDTA (ethylene diamine tetraacetic acid) complexes. Both the Pb-EDTA and Ni-EDTA complexes were chosen for study, as they represent respectivcly metals that are and are not capable of photodeposition onto the TiO2 catalyst during the photoreaction. Batch reactions were carried out in a jacketed glass pot reactor using 300 ml of 50 mg/l metal chelated with an equimolar amount of EDTA and 0.1wt% of TiO2 in the solution. The UV source used was a 100 W low-pressure Hg spot lamp. The two systems were studied using Degussa P-25 titanium dioxide, and Aldrich titanium dioxide loaded with Pt and Au. Around 80% removal of the Ni-EDTA complex was attained after 120 min using both catalysts with no photodeposition of Ni onto the catalyst. However, pH precipitation treatment of the reacted solutions indicated that the Ni was still complexed, probably to complexing agents that were EDTA oxidation products. Apparent zero-order kinetics was observed in the P-25 catalyst reaction, whereas apparent first-order kinetics was observed in the metal-loaded TiO2 catalyst. In contrast the Pb-EDTA complex was completely removed in 10 min using both catalysts. Also, complete Pb deposition onto the catalyst was attained in 30 min for both catalysts. The Pb deposition seemed to first require the degradation of the complex. Total organic carbon was reduced in the Ni-EDTA system 15-21% using both catalysts, and about 33% in the Pb-EDTA system using both catalysts. No reduction of either metal or metal complex was observed when no catalyst was present and the other conditions held constant. DOE

In a system and method for enhancing chemical reactions, a reactant is brought in contact with a stable, non-soluble, porous, electronically non-conductive solid (reaction enhancer) in a fluidic medium to form a reaction mixture of low ionic strength. The reaction mixture so formed is then subjected to an electrifying force thereby enhancing the chemical reaction. Reaction products are then collected. DTIC

SPECTRAL ELEMENT METHOD FOR NUMERICAL SIMULATION OF UNSTEADY LAMINAR DIFFUSION FLAMES Ph.D. Thesis
Richard Allen Wessel, Jr. 1993 281 p
Avail: Univ. Microfilms Order No. DA9406237

A numerical method was developed for simulation of unsteady flow with combustion. The spectral element method is used to solve the Navier-Stokes equations for conservation of mass, momentum, energy, and species. The method by Korczak and Patera was extended to include variable transport properties and Arrhenius rate chemical reaction. A variable density formulation was developed, but was found to be numerically unstable using fractional time splitting and an implicit formulation of the pressure solution to satisfy the mass continuity constraint. Therefore, the choice of constant density flow was made for practical reasons rather than physical. Time accurate simulations of a diffusion flame were conducted for initially separate co-flowing streams of fuel and oxidant in a two dimensional duct. Flow regimes and transitional states for a attached flame, unsteady attached flame, and blow-off were investigated. An increase in air velocity has the effect of making the flame shorter. Eventually the wake type flow becomes unstable and begins to oscillate. As vortices alternately form and shed from the fuel channel, the flow stretches the flame between eddies and compresses the flame within the eddies. Increasing fuel velocity effects flame detachment and subsequent blowoff as the streamwise velocity exceeds the laminar flame speed. Results are in qualitative agreement with experimental observations in the literature. Dissert. Abstr.

ON CONVECTIVE EFFECTS IN SEDIMENTATION OF CONCENTRATED SUSPENSIONS WITH HIGH EFFECTIVE GRAVITY
Jacob Ystroem 1 Dec. 1993 21 p Prepared in cooperation with Stockholm Univ., Sweden
(TRITA-NA-9316) Avail: CASI HC A03/MF A01

Momentum balance for the continuum formulation of sedimentation is considered. A linear combination of the two momentum equations is formally treated as a system of ordinary differential equations. This results in a slightly different form of Darcy's law together with a momentum equation containing convective terms. These equations together with conservation of mass and constitutive equations for colloidally stable suspensions of hard spheres are solved numerically. It is found that the discrepancy due to convective terms is independent of the Peclet number and that the effect is very small. Author

FUEL-TYPE CLASSIFICATION AND PARAMETERS PREDICTION BY GAS LIQUID CHROMATOGRAPHY ANALYSIS Final Report
Donald K. Minus Mar. 1995 84 p
(AD-A293442; TARDEC-TR-13641) Avail: CASI HC A05/MF A01

There is a research effort that envisions having a vehicle mounted petroleum analysis system that could travel close to the frontlines and would provide rapid test results. This system would quicken results feedback time and increase the scope of analyses by using new technologies that could predict several fuel properties and parameters. One approach under consideration for use in this system is Gas Liquid-Phase Chromatography (GLC). To simplify the GLC chromatograph of fuel samples, the data was collected as a series of time-segmented regions. These regions were defined to simulate separations by normal alkanes carbon chain length. The GLC data was analyzed with PIROUETTE correlation software (INFOMETRIX, Seattle, WA) to assign the fuel's type and to predict a selected number of fuel's physical properties. To conduct this study, sixty-seven (67) fuel samples were used of which fifteen were JET A-1/JET As, twelve were JP-4s, nine were JP-8s seven were MOGAS, and three were DF-2s. Preliminary results have included a 100% correct classification as to fuel type and predictions of the 10%, 50%, and 90% distillation. and final boiling point temperatures; and the densities of the samples with relatively low errors of prediction. X-RAY DIFFRACTION STUDY OF CLUSTERS IN a-tC FILMS
L. J. Martinez-Miranda (Kent State Univ., OH.), M. P. Siegal, T. A. Friedmann, J. P. Sullivan, T. W. Mercer (Drexel Univ., Philadelphia, PA.), N. J. DiNardo (Drexel Univ., Philadelphia, PA.), and F. Fang (Pennsylvania Univ., Philadelphia, PA.) 1995 8 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-010860; SAND-94-2987C; CONF-941144-144) Avail: CASI HC A02/MF A01

The authors performed an x-ray diffraction study of tetrahedral-coordinated-amorpous carbon (a-tC) films prepared by pulsed laser deposition (PLD). Samples properties were analyzed as a function of laser energy and thickness. For all thicknesses and laser energies, films were made up of clusters with a basic unit size of 7 - 11 nm. Thicker films, as well as films prepared at higher laser densities exhibit larger clusters, in the tens of nanometers. The clusters are not readily observable by AFM, which may indicate the presence of a flat (graphitized) top film surface. DOE

CONSEQUENCES OF KINETIC DISPERSION ON THE ELECTROCHEMISTRY OF AN ADSORBED REDOX-ACTIVE MONOLAYER Interim Technical Report
Gary K. Rowe, Michael T. Carter, John N. Richardson, and Royce W. Murray 1 Apr. 1995 49 p
(Contract N00014-90-J-1230)
(AD-A292794; TR-66) Avail: CASI HC A03/MF A01

Mixed monolayers of (ferrocenylcarboxy)-alkanethiol/n-alkanethiol have been investigated electrochemically in 2:1 (v:v) chloroethane:butyronitrile solvent in the temperature range of 120K to 150K. Cyclic voltammetry of these monolayers shows large oxidation-reduction peak potential separations indicative of electron transfer rate control. The voltammetric waveshapes are also broadened; this and curved log I vs. time transients observed in potential step experiments are interpreted as a dispersion in the reaction rates of the ferrocene sites. This paper considers origins and three models for such kinetic dispersion. DTIC

THE STRUCTURE AND REACTIVITY OF BORON AND CARBON SURFACES Final Technical Report, 15 Mar. 1992 - 14 Sep. 1994
Michael Trenary 22 Feb. 1995 6 p
(Contract F49620-92-J-0179)
(AD-A292804; AFOSR-95-0168TR) Avail: CASI HC A02/MF A01

Research funded by this grant focused on three areas: First, we have explored the surface chemistry associated with reactions of O2, D2O, B2O2 and B2O3 with boron thin films grown on Ta(110) through the thermal decomposition of diborane. These reactions were studied mainly with the techniques of X-ray photoelectron spectroscopy and mass analyzed thermal desorption. We find that both O2 and D2O form a B2O3-like oxide on the surface but that the oxide desorbs mainly as B2O2. Second, we have studied the reaction of B2O3 and O2 with graphitic carbon deposited on the Pt(111) surface. Although B2O3 is known to inhibit the oxidation of carbon/carbon composites, we found that B2O3 deposited on a carbon layer on Pt(111) completely removes the surface carbon by oxidizing it at 1000 K to CO(g). Although we also observe the desorption of B2O2(g) from the surface, we determined that the B2O3 is reduced in the process to elemental boron. Third, we finished some experiments during the first few months of the grant on the oxidation of the LaB6(100) surface. DTIC

AN ANALYSIS OF GAS PHASE ETHANOL/WATER CHEMISTRY FOR DIAMOND CVD
Robert S. Sinkovits, Richard C. DeVore, Vasgen A. Shamamian, and Charles K. Westbrook 29 Mar. 1995 46 p
(AD-A293009; NRL/MR/6410-95-7662) Avail: CASI HC A03/MF A01

Chemical kinetics calculations have been carried out on ethanol (EtOH)water mixtures at a range of temperatures, pressures and EtOH/H2O ratios. The results show that the mole fractions of many chemical species depend very sensitively on the initial EtOH/H20 ratio and diverge sharply after an induction time which depends both on pressure and temperature. We explain this divergence primarily in terms of the stability of carbon monoxide and show that the rate-limiting steps that dictate the induction time are the molecular hydrogen dissociation reactions. Our calculations also predict the dependence of the concentrations of potential growth (C, CH3, C2H2) and etching (O, OH, O2) species for diamond chemical vapor deposition (CVD) on operating conditions. EVALUATION OF HALON ALTERNATIVES IN INERTING EXPERIMENTS Final Report, Oct. 1992 - Dec. 1994
Anthony E. Finnerty and Dawnn M. Saunders Apr. 1995 33 p
(AD-A293774; ARL-TR-733) Avail: CASI HC A03/MF A01

Inerting experiments were conducted in a 20-liter stainless steel chamber. Eight potential Halon 1301 replacement agents were used to inert butane-air mixtures. The agents were ranked on the amount required to completely inert the system and on their tendencies to form hydrogen fluoride. A specific ion electrode was used to determine the amount of hydrogen fluoride formed when less than the amount of agent required for complete inertion was used in an experiment. The two iodine-containing agents, perfluoroethyl iodide and perfluoromethyl iodide, were superior to the other potential replacement agents in that less concentration was required for inertion and less hydrogen fluoride formed than with the others. The ability of perfluoroethyl iodide and perfluoromethyl iodide, which are chemical fire-extinguishing agents, to act as inerting agents is attributed to the ease of breaking of the relatively weak (ca. 57 kcal/mole) carbon to iodine bond at low temperatures. This enabled the iodine-containing agents to act as energy-absorbing agents, which is important in preventing ignition of fuel-air-agent mixtures. DTIC

RATIONALE AND SUMMARY OF METHODS FOR DETERMINING ULTRASONIC PROPERTIES OF MATERIALS AT LAWRENCE LIVERMORE NATIONAL LABORATORY
A. E. Brown Feb. 1995 36 p
(Contract W-7405-eng-48)
(DE95-009475; UCRL-ID-119958) Avail: CASI HC A03/MF A01

This report is a summary of the methods used to determine ultrasonic velocities through the many materials tested at the Acoustic Properties of Materials Laboratory. Ultrasonic velocity techniques enable the determination of material properties, including elastic moduli, without harming the materials being tested, an advantage some over mechanical methods. Ultrasonic modulus determination has other advantages as well: (1) relative ease and low cost of material preparation; and (2) comparative analysis to physical testing as a function of material loading rate dependence. In addition, ultrasonic measurement provides clues to determine grain size and orientation, and provides a relative indication of material anisotropy with respect to the material geometry. The authors usually perform ultrasonic measurements on materials in ambient atmospheric conditions, and in a relatively free-free condition. However, the authors can perform them in other environments, as required. This paper describes some of the techniques used in this laboratory and shows how ultrasonic velocities are used to establish elastic constants. It also includes a sample test report for a homogeneous isotropic solid. DOE

A THEORETICAL TREATMENT OF THE ABSORPTION AND EMISSION PROPERTIES OF Cu(2) PORPHYRIN Interim Report
Krassimir K. Stavrev and Michael C. Zerner 18 Apr. 1995 21 p
Submitted for publication in the Chem. Phys. Letters
(Contract N00014-90-J-1608)
(AD-A293669; TR-30) Avail: CASI HC A03/MF A01

We examine the electronic spectrum of Cu(2) Porphyrin using the Intermediate Neglect of Differential Overlap (INDO) model that has been specifically parametrized for spectroscopy at the configuration interaction level of theory. The isolated molecule is predicted to have a trip-doublet absorption, corresponding to porphyrin triplets, at about 9,000/cm and 13,900/cm. The Q band is calculated at 15,900/cm, in good accord with experimental values. We predict a normal emission in this case, as is

observed. We find that chelating in the fifth position with a strong ligand such as pyridine leads to a state in energy below the Q band that is mostly d(z squared) greater than d(x squared-y squared) but with appreciable a2u(Pi) greater than d(x squared-y squared) character. We postulate that it is the presence of this state that quenches the emission when Cu(2) porphyrins are complexed with strong fifth or fifth and sixth position ligands. DTIC

CALCULATED STRUCTURES AND ELECTRONIC ABSORPTION SPECTROSCOPY FOR MAGNESIUM PHTHALOCYANINE AND ITS ANION RADICAL Interim Report
Marshall G. Cory, Horoaki Hirose, and Michael C. Zerner 19 Apr. 1995 39 p Submitted for publication in the Inorg. Chemistry
(Contract N00014-90-J-1608)
(AD-A293672; TR-33) Avail: CASI HC A03/MF A01

Structures are calculated for Magnesium Phthalocyanine (MgPc) and its radical anion doublet (MgPc-), using both ab-initio (6-13G**) and semiemperical (INDO/1) self-consistent field approaches. The anion is first order Jahn-Teller distorted, and the various distortions that are possible are examined. The electronic absorption spectra of both molecular species, and the effect varying the degree of distortion has on the computed anion spectrum are diacussed. These results suggest that the four-orbital model often applied to porphyrin systems in interpreting the low energy spectrum is incomplete for the anion case. We further conclude that the Jahn-Teller distortions calculated by either ab-initio or semiemperical models may be too great. DTIC

DIFFERENCES IN CREEP PERFORMANCE OF A HIPED SILICON NITRIDE IN AMBIENT AIR AND INERT ENVIRONMENTS
A. A. Wereszczak, T. P. Kirkland, and M. K. Ferber 1995 9 p Presented at the 19th Annual Conference on Advanced Ceramics, Materials and Structures, Cocoa Beach, FL, 9-12 Jan. 1995
(Contract DE-AC05-84OR-21400)
(DE95-009172; CONF-950129-3) Avail: CASI HC A02/MF A01

High temperature tensile creep studies of a commercially available hot isostatically pressed (HIPed) silicon nitride were conducted in ambient air and argon environments. The creep performance of this HIPed silicon nitride was found to be different in these environments. The material crept faster (and had a consequentially shorter lifetime) in argon than in ambient air at 1370 C at tensile stresses between 110-140 MPa. The stress dependence of the minimum creep rate was found to be approx. 6 in argon and approx. 3.5 in air, while the minimum creep rates were almost an order of magnitude faster in argon than in air at equivalent tensile stresses. Differences in the creep performance are explained with reference to the presence or absence of oxygen in the two environments. DOE

THE NASA/JPL EVALUATION OF OXYGEN INTERACTIONS WITH MATERIALS-3 (EOIM-3) Final Report
David E. Brinza, Shirley Y. Chung, Timothy K. Minton, and Ranty H. Liang Dec. 1994 107 p Original contains color illustrations
(Contract NAS7-1260; RTOP 233-03-02-08-28)
(NASA-CR-198865; JPL-Publ-94-31; NAS 1.26:198865) Avail: CASI HC A06/MF A02; 2 functional color pages

The deleterious effects of hyperthermal atomic oxygen (AO) found in low-earth-orbit (LEO) environments on critical flight materials has been known since early shuttle flights. This corrosive effect is of considerable concern because it compromises the performance and longevity of spacecraft/satellite materials deployed for extended periods in LEO. The NASA Evaluation of Oxygen Interactions with Materials-3 (EOIM-3) experiment served as a testbed for a variety of candidate flight materials for space assets. A total of 57 JPL test specimens were present in six subexperiments aboard EOIM-3. In addition to a number of passive exposure materials for flight and advanced technology programs, several subexperiments were included to provide data for understanding the details of atomic oxygen interactions with materials. Data and interpretations are presented for the heated tray, heated strips, solar ultraviolet exposure, and scatterometer subexperiments, along with a detailed description of the exposure conditions experienced by materials in the various experiments. Mass spectra of products emerging from identical samples of a (sup 13)C-enriched polyimide polymer (chemically equivalent to Kapton) under atomic oxygen bombardment in space and in the laboratory were collected. Reaction products unambiguously detected in space were (sup 13)CO, NO, (sup 12)CO2, and (sup 13)CO2. These reaction products and two others, H2O and (sup 12)CO, were detected in the laboratory, along with inelastically scattered atomic and molecular oxygen. Qualitative agreement was seen in the mass spectra taken in space and in the laboratory; the agreement may be improved by reducing the fraction of O2 in the laboratory molecular beam. Author

ABSORPTION AND IONIZATION SPECTRA OF MODEL RUBREDOXINS
Krassimir K. Stavrev and Michael C. Zerner 18 Apr. 1995 17 p Submitted for publication in the Intern. J. Quantum Chem.
(Contract N00014-90-J-1608)
(AD-A293668; TR-31) Avail: CASI HC A03/MF A01

We examine here spectroscopic properties of oxidized rubredoxin (Rdx) within the intermediate neglect of differential overlap method parameterized for spectroscopy. The Rdx structures are modeled using different length -SR residues bound to the Fe atom and the resulting effect on the absorption spectrum is examined. The corresponding ionization potentials are also calculated and their dependence on the molecular charge is studied. This study suggests that models used to reproduce the redox properties of these important electron-transfer compounds must be carefully chosen. DTIC

THE STUDY OF FLAME-VORTEX INTERACTIONS USING A PARTICLE IMAGE VELOCIMETER Ph.D. Thesis
David A. Nye 1993 201 p
Avail: Univ. Microfilms Order No. DA9414347

An experiment has been devised to examine the evolution of flame stretch, flame curvature, and flow strain rate during the interaction of a premixed (lean, methane-air) laminar V-flame and a Karman Vortex Street. The experimental technique relies heavily upon the use of a particle image velocimeter both to make strain rate measurements and also to quantify vortex structure. Thirty flame realizations are studied at a single operating condition. A sequence of events occurring during the interaction was constructed from flow visualization results and flame stretch measurements. A large region of positive flame curvature (convex to the reactants) bordered by cusps (small areas of large negative curvature) is formed by a pair of counter-rotating vortices that produces a local velocity deficit into which the flame propagates. The action of the flame tends to spread the pair apart while distorting and weakening individual vortices, thus signaling the end of the interaction. Velocity, vorticity, flame stretch rate, flame curvature, and flame strain rate plots are provided for several realizations. In addition, probability density functions (pdf) and scatter plots for these quantities are provided for the entire set of thirty flame realizations. Scatter plots indicate that the flame curvature and flow strain rate are found to be statistically independent, and that the average flame stretch rate for an individual flame is determined directly from the average flame curvature. Average flow strain is found to be nearly zero in accordance with the periodic flow pattern surrounding the vortex street. Results further indicate that flame properties such as flame speed and temperature will not be significantly affected by flame stretch. This condition provides an ideal baseline comparison for additional PIV system measurements and is an excellent test case for numerical code development. Comparison between these results and the action of large scales in premixed turbulent combustion is

also discussed. The action flow scales much larger than the flame thickness in a turbulent flame is inferred from the interaction of laminar vortices with a laminar flame front. Dissert. Abstr.

COMBUSTION OF LOX WITH H2(SUB g) UNDER SUBCRITICAL AND SUPERCRITICAL CONDITIONS Ph.D. Thesis
An-Shik Yang 1993 145 p
Avail: Univ. Microfilms Order No. DA9414403

The objective of this investigation is to study the evaporation and combustion of LOX under supercritical and subcritical conditions both experimentally and theoretically. In the evaporation studies, evaporation rate and surface temperature were measured when LOX vaporizing in helium environments at pressures ranging from 5 to 68 atm. A Varian 3700 gas chromatograph was employed to measure the oxygen concentration above the LOX surface. For the combustion tests, high magnification video photography was used to record direct images of the flame shape of a LOX/H2/He laminar diffusion flame. The gas composition in the post-flame region was also measured with the gas sampling and chromatography analysis. These data can be used to validate the theoretical model. A comprehensive theoretical model with the consideration of the solubility of ambient gases as well as variable thermophysical properties was formulated and solved numerically to study the gasification and burning of LOX at elevated pressures. The calculated flame shape agreed reasonably well with the edge of the observed luminous flame surface. The effect of gravity on the flame structure of laminar diffusion flames was found to be significant. In addition, the predicted results using the flame sheet model were compared with those based upon full equilibrium calculations (which considered the formation of intermediate species) at supercritical pressures. Except at the flame front where temperature exceeded 2,800 K, the flame-sheet and equilibrium solutions in terms of temperature distributions were in very close agreement. The temperature deviation in the neighborhood of the flame front is caused by the effect of high-temperature dissociation. Dissert. Abstr.

NON-INTRUSIVE COMBUSTION DIAGNOSTICS OF PREMIXED HYDROCARBON FLAMES USING FT-IR SPECTROMETRY Ph.D. Thesis
I.-Te Huang 1993 122 p
Avail: Univ. Microfilms Order No. DA9414304

Many of the current limitations in the knowledge of combustion of hydrocarbon fuels can be attributed to the inability to experimentally probe the flame zone of such fuels. As a result, there has been a considerable effort devoted to the development of both intrusive and nonintrusive diagnostic techniques. Intrusive techniques have limitations which include, among others, the following: (1) disturbances are introduced in the medium; (2) the probe is consumed by the hostile environment; and (3) the temporal response and spatial resolution are typically insufficient to follow the event. In this work, the use of FT-IR spectrometry for probing nonintrusively the premixed flame zone of hydrocarbon flames is described. The application of this technique yields spatial profiles of temperature, species concentrations, and relative soot concentration. Fuel-rich methane/oxygen/nitrogen flames are used to develop the combustion diagnostic technique. A Fortran package, PREMIX, which is capable of predicting temperature and species concentration profiles using user-supplied chemical kinetic information, is utilized for comparison purposes and to obtain information of major chemical reactions. Studies of liquid hydrocarbon fuels, such as benzene and toluene, are also proposed. Dissert. Abstr.

EFFECTS OF GAS-PHASE THERMAL EXPANSION ON THE STABILITY OF DEFLAGRATION THROUGH A POROUS ENERGETIC MATERIAL
S. B. Margolis and F. A. Williams (California Univ., San Diego, La Jolla, CA.) 1995 42 p Presented at the 30th AIAA/SAE/ASME Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995
(Contract DE-AC04-94AL-85000)
(DE95-004382; SAND-95-8456C; CONF-950720-1) Avail: CASI HC A03/MF A01

The propagation of a deflagration wave through porous energetic materials, as in the case of strictly condensed-phase combustion, is subject to intrinsic diffusional/thermal instabilities that can lead to various oscillatory modes of burning. Under the assumption that the gas phase may be regarded as ideal but quasi-steady, asymptotic analyses are developed for the nonsteady, nonplanar deflagration of porous energetic solids, such as degraded nitramine propellants, that experience significant gas flow in the solid preheat region and are characterized by the presence of exothermic reactions in a bubbling melt layer at their surfaces. Relative motion between the gas and condensed phases is taken into account in both regions, and the derived asymptotic model is analyzed to obtain an explicit solution for steady, planar deflagration and a dispersion relation describing its linear stability. The present analysis parallels a similar study by the authors that allowed for a fully nonsteady gas phase, but neglected the effects of gas-phase thermal expansion. Nonetheless, qualitatively similar results are obtained, predicting a pulsating neutral stability boundary in the nondimensional activation energy - disturbance wavenumber plane beyond which nonsteady, nonplanar solutions are anticipated. Focusing on the realistic limit of small ratios of gas-phase to condensed-phase density and thermal conductivity, it is demonstrated that the effect of a nonzero porosity alpha(sub s) of the unburned solid material is generally destabilizing, by an amount proportional to alpha(sub s) (1 - alpha(sub s))(exp -1), relative to the nonporous case. The effect of gas-phase thermal expansion is also shown to be destabilizing, further suggesting that degraded propellants, which exhibit greater porosity than the pristine material, may be especially prone to nonsteady deflagration. ON THE JAHN-TELLER EFFECT OF Mn(2+) IN ZINC-BLENDE ZnS CRYSTAL Interim Report
Krassimir K. Stavrev and Michael C. Zerner 18 Apr. 1995 26 p
(Contract N00014-90-J-1608)
(AD-A293711; TR-29) Avail: CASI HC A03/MF A01

The excited states of Mn(2+) in zinc-blende ZnS crystal have been studied by the Intermediate Neglect of Differential Overlap model parameterized for spectroscopy (INDO/S) within the Restricted Open-Shell Hartree-Fock (ROHF)-Configuration Interaction (CI) approximation. The effect of the Jahn-Teller (JT) active e-mode on the first excited state (a(4)T1) has been examined with respect to energy barriers and geometric distortions. The dynamical JT effect has been studied and the excited state absorption (ESA) profiles for different e-mode conformations have been calculated. Good reproduction of the experimental ESA spectrum has been obtained for nuclear arrangements corresponding to small S-Mn-S angle distortions. The off-center Tau 2-mode vibrations were found to promote the JT coupling by reducing the barriers between the stable structures. DTIC

DETERMINATION OF HALOGENS IN A PETROLEUM PRODUCT BY ION CHROMATOGRAPHY
H. L. Tucker 15 Jul. 1994 7 p Presented at the 36th Rocky Mountain Conference on Analytical Chemistry, Denver, CO, 31 Jul. - 5 Aug. 1995
(Contract DE-AC05-84OS-21400)
(DE95-002056; Y/DK-1043; CONF-950737-1) Avail: CASI HC A02/MF A01

A rapid, high-performance ion chromatography (HPIC) method with isocratic separation and the anion self-regenerating suppressor (in the chemical suppression mode, specifically for the determination of fluoride, chloride, bromide, and iodide in a petroleum product) is discussed. This is a proposed new method for a production laboratory within the Analytical Services Organization at the Oak Ridge Y-12 Plant. DOE

FASTER, CHEAPER RADIOANALYTICAL METHODS
M. D. Erickson, J. H. Aldstadt, J. S. Alvarado, J. S. Crain, K. A. Orlandini, and L. L. Smith 1995 8 p Presented at the Waste Management 1995 Conference, Tucson, AZ, 26 Feb. - 2 Mar. 1995
(Contract W-31-109-eng-38)
(DE95-009913; ANL/ER/CP-84530; CONF-950216-115) Avail: CASI HC A02/MF A01

This project focuses on improvement of radioanalytical methods, with an emphasis on faster and cheaper routine methods. The authors have developed improved methods for the separation of environmental levels of technetium-99, radium, and actinides from soil and water; separation of actinides from soil and water matrix interferences; and isolation of strontium.

Among the novel techniques for separation that are being used are element and class-specific resins and membranes. The authors have also developed methods for the simultaneous detection of multiple isotopes by using inductively coupled plasma-mass spectrometry (ICP-MS). Because of its mass-selective mode of detection, ICP-MS requires less rigorous chemical separations than does radiochemical analysis. In addition, improvements in the limits of detection, the volume of the sample and the time of analysis were obtained by using other techniques of sample introduction, such as ultrasonic nebulization, automated batch separation and electrothermal vaporization. Investigation of integration and automation of the separation methods with the ICP-MS method using flow injection analysis is underway. A solid scintillation device has been developed and tested for measurement and identification of low-energy beta-emitting radionuclides; application of this technique will eliminate the generation of mixed-waste counting cocktails. The final product of all activities will be methods that are available and are acceptable for use in regulatory situations. Concerted efforts are being made to facilitate implementation of the methods at DOE sites to realize the improvements offered. DOE

ULTRASENSITIVE FLUORESCENCE DETECTION AND PHOTOPHYSICS IN MICRODROPLETS

Michael D. Barnes, William B. Whitten, and J. Michael Ramsey 1995 10 p Presented at the SPIE 1995: SPIE Conference on Optics, Electro-óptics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995

(Contract DE-AC05-84OR-21400)

(DE95-010283; CONF-950226-36) Avail: CASI HC A02/MF A01

Fluorescence detection of single molecules in room temperature liquids is usually plagued by many difficulties such as finite saturated absorption rate, finite laser-analyte interaction time, and analyte diffusion. Our approach to single molecule detection in liquids has been to use microdroplets as the sample medium which has many advantages over conventional 'bulk' techniques such as extended laser-analyte interaction time, a probe volume defined by the droplet, and modified radiative properties of molecules due to interactions with droplet resonances. We have demonstrated detection of single rhodamine molecules with signal-to-noise ratios on the order of 30 using levitated microdroplets as the sample medium. The focus of current work is on single molecule detection in falling droplet streams with analysis rates on the order of 5-10 kHz. DOE

LLW SOLIDIFICATION IN CEMENT: EFFECT OF DILUTION

A. A. Kruger, A. Katz, A. R. Brough, T. Bakharev, R. J. Kirkpatrick, L. J. Struble, and J. F. Young Feb. 1995 8 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994

(Contract DE-AC06-87RL-10930)

(DE95-010108; WHC-SA-2675; CONF-941144-120) Avail: CASI HC A02/MF A01

A simulated Low Level nuclear Waste (LLW) solution was tested for long term solidification in a cement-based matrix. The waste is characterized by high pH and high concentrations of sodium, aluminum, nitrate, nitrite, phosphate and carbonate. The effect of diluting the waste with additional water was studied. The cementitious matrix was composed of cement, fly-ash and clay (21%, 68% and 11% respectively) with high solution to solid ratio (1 liter /1 kg.). Mixes were prepared at 45 C and cured at 90 C for 28 days. Maximum 28 day compressive strengths and early age heat evolution were achieved by diluting the LLW solution to approximately 67% of its original concentration. More dilution led to a lower heat evolution and compressive strength. No dilution was found to give lower compressive strength, and a heat evolution that was delayed, and lower in intensity. XRD spectra showed formation of zeolites and tobermorite at the higher concentrations (67, 85, and 100% of the concentration of the undiluted simulated LLW), with a change from Na-PI zeolite for 67% of the undiluted concentration to a sodalite at 100%. SEM observations showed a porous system for the low and high dilution rates but a less porous one for an intermediate level of dilution. DOE

THE THEORETICAL CALCULATION OF VIBRATIONAL CIRCULAR DICHROISM SPECTRA Final Report, 1 Jan. 1993 - 1 Sep. 1994

P. J. Stevens, F. J. Devlin, C. S. Ashvar, C. F. Chabalowski, and M. J. Frisch Apr. 1995 48 p Prepared in cooperation with University of Southern California, Los Angeles, and Lorentzian, Inc., North Haven, CT

(DA Proj. 1L1-61102-AH-43)

(AD-A293614; ARL-TR-732) Avail: CASI HC A03/MF A01

We report calculations of the mid-IR unpolarized absorption and circular dichroism spectra of 4-methyl-2-oxetanone, 6,8-dioxabicyclo (3.2.1) octane and 1,7,7-trimethylbicyclo (2.2.1) heptan-2-one (camphor) based on harmonic force fields calculated using Density Functional Theory (DFT). A hybrid density functional -- Becke3LYP -- is used. The basis set is 6-31G. The results are in impressive agreement with experimental spectral calculations using the LSDA and BLYP functionals are much less successful. Our results using Becke3LYP/DFT are compared to the predictions of SCF and MP2 calculations. At the present time, the Becke3LYP/DFT methodology is clearly to be preferred in predicting mid-IR vibrational spectra. DTIC

LABORATORY ROBOTICS: AN AUTOMATED TOOL FOR PREPARING ION CHROMATOGRAPHY CALIBRATION STANDARDS

James L. Chadwick 1995 11 p Presented at the Pittsburgh Conference and Exhibition on Analytical Chemistry and Applied Spectroscopy: Stimulating the Minds of Today's and Tomorrow's Scientists, New Orleans, LA, 5-10 Mar. 1995

(Contract DE-AC11-93PN-38195)

(DE95-009441; WAPD-T-3041; CONF-950389-1) Avail: CASI HC A03/MF A01

This paper describes the use of a laboratory robot as an automated tool for preparing multi-level calibration standards for On-Line Ion Chromatography (IC) Systems. The robot is designed for preparation of up to six levels of standards, with each level containing up to eleven ionic species in aqueous solution. The robot is required to add the standards' constituents as both a liquid and solid additions and to keep a record of exactly what goes into making up every standard. Utilizing a laboratory robot to prepare calibration standards provides significant benefits to the testing environment. These benefits include: accurate and precise calibration standards in individually capped containers with preparation traceability; automated and unattended multi-specie preparation for both anion and cation analytical channels; the ability to free up a test operator from a repetitive routine and re-apply those efforts to test operations; The robot uses a single channel IC to analyze each prepared standard for specie content and concentration. Those results are later used as a measure of quality control. System requirements and configurations, robotic operations, manpower requirements, analytical verification, accuracy and precision of prepared solutions, and robotic downtime are discussed in detail. WASTE MINIMIZATION VIA PREPARATIVE SCALE HIGH PERFORMANCE GEL PERMEATION CHROMATOGRAPHY

Amrit S. Boparai, Kathleen J. Parish, Stephen D. Kent, Yifen Tsai, and David A. Joe 1995 16 p Presented at the Pittsburgh Conference and Exhibition on Analytical Chemistry and Applied Spectroscopy: Stimulating the Minds of Today's and Tomorrow's Scientists, New Orleans, LA, 5-10 Mar. 1995

(Contract W-31-109-eng-38)

(DE95-011797; ANL/CMT-ACL/VU-83809; CONF-950389-2-Vugraphs)

Avail: CASI HC A03/MF A01

The procedures developed here allow removal of radioactivity, as judged by removal of (sup 152)Europium (III) from methylene chloride solutions of CLP analytes without significantly reducing recovery of organic compounds. This allows analysis of nonradioactive extracts on instrumentation maintained in a regular nonradioactive laboratory, resulting in a significant savings in cost. DOE

SYNTHESIS OF SEPARATION SYSTEMS: METHODS AND APPLICATIONS IN DOWNSTREAM GAS PROCESSES

J. Sogge 1994 111 p

(PB95-208518; STF21-A94014) Avail: Issuing Activity (National Technical Information Service (NTIS))

In this work, the different separation processes applied in the downstream gas processing industry for separation of gaseous products have been described based upon information found in the literature. Furthermore, an overview of characteristics, simple design considerations/methods and cost data of the different gas separation technologies (e.g. distillation) has been made. The main purpose of this work is to increase the level of competence within synthesis of gas separation systems. The increased competence can be utilized to enhance the quality of the technical and economic evaluations of petrochemical processes, where the separation systems greatly influences the economics of these processes. MECHANICAL ALLOYING PROCESSING WITH APPLICATION TO STRUCTURAL MATERIALS Final Report, 1 Feb. 1993 - 30 Sep. 1994
T. H. Courtney 26 Sep. 1994 13 p
(Contract DAAH04-93-G-0057)
(AD-A290788; ARO-30920.9-MS) Avail: CASI HC A03/MF A01

This report summarizes efforts and accomplishments relative to modeling of the mechanical alloying processing and in synthesis and consolidation of structural materials made by mechanical alloying. Models depicting the extent of deformation and the fracture and welding frequencies of powders subjected to mechanical alloying are encapsulated. A description of an improved attritor processing scheme is given. In addition, we describe the means of synthesizing nanocermets of the Cu-NbC system. The structure and properties of these materials are described, as they are know at this time. Finally, a description of consolidated heavy metals and their properties as they are found when prepared from mechanically alloyed precursor powders is given. DTIC

WETTABILITY OF BORON CARBIDE
T. Torvund, O. M. Akselsen, O. Grong, and J. H. Ulvensoen 2 Jun. 1994 13 p
(PB95-196358; STF24-S94001) Avail: Issuing Activity (National Technical Information Service (NTIS))

The work was presented at the conference, Advanced Joining Technologies for New Materials II, which was held in Cocoa Beach, USA, 2-4 March. The conference proceedings will be published in 1994. The wettability of boron carbide has been examined by means of the sessile drop method, using the following candidate alloys: (96 wt percent Ag - 4 wt percent Ti), (Ag - 26.5 wt percent Cu - 3 wt percent Ti), (Sn - 10 wt percent AG - 4 wt percent Ti), Sn(99.95 wt percent) and Al(99.99 wt percent). The results show that B4C is completely wetted by the Ag-based alloys. Sn - 10 wt percent Ag - 4 wt pecrent Ti alloy and pure Al partly wet the B4C surface, while pure Sn does not wet B4C at all. Improvements in high temperature oxidation resistant metal coating technology will allow NASA and commercial entities to develop competitive civil space transport and communication systems. The success of investigations completed in this program will have a positive impact on broadening the technology base for high temperature materials. The work reported herein describes processes and procedures for successfully depositing coherent oxidation barrier coatings on refractory metals to prevent degradation under very severe operating environments. Application of the new technology developed is now being utilized in numerous Phase 3 applications through several prominent aerospace firms. Major achievements have included: (1) development of means to deposit thick platinum and rhodium coatings with lower stress and fewer microcracks than could be previously achieved; (2) development of processes to deposit thick adherent coatings of platinum group metals on refractory substrates that remain bonded through high temperature excursions and without need for intermediate coatings (bonding processes unique to specific refractory metals and alloys have been defined; (3) demonstration that useful alloys of refractory and platinum coatings can be made through thermal diffusion means; (4) demonstration that selected barrier coatings on refractory substrates can withstand severe oxidizing environments in the range of 1260 deg and 1760 deg C for long time periods essential to the life requirements of the hardware; and (5) successful application of the processes and procedures to prototype hardware. The results of these studies have been instrumental in improved thermal oxidation barrier coatings for the NASP propulsion system. Other Phase 3 applications currently being exploited include small uncooled thrusters for spacecraft and microsatellite maneuvering systems. Author

OBSERVATION OF A LOW-BINDING-ENERGY PEAK IN THE 2p CORE-LEVEL PHOTOEMISSION FROM OXIDIZED Al(111)
C. Berg, S. Raaen, A. Borg, J. N. Andersen, and E. Lundgren 19 May 1994 6 p Prepared in cooperation with Lund Univ., Sweden and Technical Univ. of Norway, Trondheim
(PB95-195350; STF19-S94004) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

High-resolution photoemission studies of oxidation of the Al(111) surface have been performed. The appearance of a component at lower binding energy than the metallic bulk Al emission in the Al 2p spectrum at oxygen exposures above approx. 50 langmuir (1 L = 10(exp -6) Torr s) is argued to be due to Al atoms which do not bond directly to oxygen atoms at the oxide-metal interface. Low-energy electron diffraction initially shows a 1 x 1 structure, which subsequently fades away at higher oxygen exposures, approximately equal or greater than or 400 L. NTIS

APPLICATIONS OF SXPS FOR STUDYING SURFACE STRUCTURE, REACTION MECHANISMS AND KINETICS
D. R. Mullins, D. R. Huntley, and S. H. Overbury 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contracts DE-AC05-84OR-21400; DE-AC02-76CH-00016)
(DE95-008903; CONF-941144-94) Avail: CASI HC A02/MF A01

Soft x-ray photoelectron spectroscopy (SXPS) from the S 2p core level has been used to study adsorbate induced reconstruction, identify reaction intermediates and study reaction kinetics on the Ni(111) surface. The S 2p binding energy is affected by the nature of the surface adsorption site. It has been determined from the number of S 2p states and their relative binding energies that adsorbed S induces a reconstruction of the Ni(111) surface and that the S adsorbs in fourfold sites on terraces and in troughs. S 2p SXPS has also been used to identify adsorbed species during the thermal decomposition of methanethiol on Ni(111). CH3SH adsorbs as CH3S(minus) at low temperatures. Above 200 K, the CH3S(minus) changes adsorption site and the C-S bond begins to cleave. The relative concentrations of CH3S(minus) in the two different sites and of atomic S have been monitored as a function of temperature and initial coverage. As a result of the sensitivity and resolution available in SXPS, reaction rates and kinetic parameters have been obtained for the decomposition of benzenethiol on Ni(111) by monitoring the changes in the surface composition continuously as a function of temperature and time. TRIVALENT CHROMIUM SOLUTIONS FOR SEALING ANODIZED ALUMINUM Patent
Fred Pearlstein, inventor (to Navy) and Vinod S. Agarwala, inventor (to Navy) 20 Dec. 1994 7 p Filed 1 Oct. 1993
(AD-D017349; US-Patent-5,374,347; US-Patent-Appl-SN-134762; US-Patent-Class-205-203) Avail: US Patent and Trademark Office

Corrosion resistant seal-coatings are formed on anodized aluminum by immersion in aqueous solutions containing trivalent chromic compounds with an alkali added near or slightly beyond the precipitation of insoluble basic compounds. Trivalent chromium seals formed on the anodized aluminum when tested in 5% NaCl salt spray chamber showed improved corrosion resistance. After a post-treatment in a peroxide or permanganate solution, the corrosion resistance for the anodized aluminum showed even greater improvement in the salt chamber. DTIC

HIGH-TEMPERATURE OXIDATION BEHAVIOR OF IRIDIUM-RHENIUM ALLOYS
Brian D. Reed Jul. 1995 15 p Presented at the 30th Joint Propulsion Conference, Indianapolis, IN, 27-29 Jun. 1994; sponsored by AIAA, ASME, SAE, and ASEE
(RTOP 506-42-31)
(NASA-TM-106720; E-9086; NAS 1.15:106720) Avail: CASI HC A03/MF A01

The life-limiting mechanism for radiation-cooled rockets made from iridium-coated rhenium (Ir/Re) is the diffusion of Re into the Ir layer and the subsequent oxidation of the resulting Ir-Re alloy from the inner surface. In a previous study, a life model for Ir/Re rockets was developed. It incorporated Ir-Re diffusion and oxidation data to predict chamber lifetimes as a function of temperature and oxygen partial pressure. Oxidation testing at 1540 deg C suggested that a 20-wt percent Re concentration at the inner wall surface should be established as the failure criterion. The present study was performed to better define Ir-oxidation behavior as a function of Re concentration and to supplement the data base for the life model. Samples ranging from pure Ir to Ir-40 wt percent Re (Ir-40Re) were tested at 1500 deg C, in two different oxygen environments. There were indications that the oxidation rate of the Ir-Re alloy increased significantly when it went from a single-phase solid solution to a two-phase mixture, as was suggested in previous work. However, because of testing anomalies in this study, there were not enough dependable oxidation data to definitively raise the Ir/Re rocket failure criterion from 20-wt percent Re to a Re concentration corresponding to entry into the two-phase region. EFFECTS OF TEMPERATURE RAMP RATE DURING HEAT TREATMENT ON HYSTERESIS LOSS AND CRITICAL CURRENT DENSITY OF INTERNAL TIN PROCESSED WIRES
M. Suenaga and R. L. Sabatini 1995 4 p Presented at the 9th US/Japan Workshop on High-field Superconducting Materials, Kyoto, Japan, 11-16 Mar. 1995
(Contract DE-AC02-76CH-00016)
(DE95-009551; BNL-61242; CONF-9503127-1) Avail: CASI HC A01/MF A01

It has been shown that temperature ramp rates utilized in heat treatment schedules for internal tin processed Nb3Sn wires substantially influence both hysteresis loss and critical current density J(sub c) of the wires, i.e. a slow ramp rate (e.g. 6(degree)C/h) favors a higher J(sub c) while a fast ramp (e.g. 60(degree)C/h) results in a low hysteresis loss of the wire. DETERMINATION OF SITE-OCCUPANCIES IN ALUMINIDE INTERMETALLICS BY ALCHEMI
I. M. Anderson, J. Bentley, and A. J. Duncan (Florida Univ., Gainesville, FL.) 1995 7 p Presented at the 1994 Fall Meeting of the Materials Research Society, Boston, MA, 28 Nov.- 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-009179; CONF-941144-117) Avail: CASI HC A02/MF A01

The site-distributions of Fe in four B2-ordered NiAl-based alloys with Fe concentrations of 10%, 2%, and 0.5% have been determined by ALCHEMI (atom-location by channeling-enhanced microanalysis). Site-distributions have been extracted with standard errors between approximately 1.5% (10% Fe concentration) and approximately 6% (0.5% Fe concentration). The results show that Fe has no strong site-preference in NiAl and tends to reside on the site of the stoichiometrically deficient host element. An improved ALCHEMI analysis procedure is outlined. The analysis explicitly addresses the phenomenon of ionization delocalization, which previously complicated the determination of site-distributions in aluminide intermetallics, leading to inaccurate and oftentimes nonphysical results. The improved ALCHEMI analysis also addresses the presence of anti-site defects. The data acquisition conditions have been optimized to minimize the sources of statistical and systematic error. This optimized procedure should be suitable for all analyses of B2-ordered alloys. Several analyses at different channeling orientations show that the extracted site-occupancies are robust as long as the data are acquired at orientations that are remote from any major pole of the crystal. DOE

DISSOLUTION OF EUTECTIC MICROSTRUCTURES Ph.D. Thesis
C. Nordlund 10 Feb. 1995 74 p
(Contract W-7405-eng-82)
(DE95-010244; IS-T-1718) Avail: CASI HC A04/MF A01

Literature review of microstructural development during melting revealed comprehensive work on interface stability but only observations of two-phase melting, including eutectic systems, with no analytical work. Four analytical models were developed to establish the role of solute diffusion and surface energy on morphology of a directionally melted lamellar eutectic. First, a mass balance of solute provided solute profile equations for the cases of no diffusion and complete diffusion in the liquid. Second, an energy balance at the interface provided separate equations for the average mp of each phase vs velocity, lamellar spacing, and material constants. Third, the diffusion equation was solved for a planar melting interface (solving for the average temperature of interface and combining with solute profile allowed solution of interface shape). Finally, a balance of the normal solute flux at the interface was used to examine the relation between interface morphology and solute diffusion in the liquid and solid. Experiments were conducted using a transparent organic lamellar eutectic alloy in which the melting interface could be observed in-situ. Steady-state interface morphologies were compared with predictions of solution of diffusion equation. Most experiments fitted the predicted morphologies, with exceptions where diffusive coupling was not maintained and a nonisothermal, nonplanar interface resulted. Experiment also revealed interface instabilities, including brief periods of a single phase planar interface and a Rayleighian instability for the nonplanar morphologies. DOE

EVALUATION ON MATERIALS PERFORMANCE OF HASTELLOY ALLOY XR FOR HTTR USES. 4: TENSILE PROPERTIES OF BASE METALS AND WELDED JOINTS
Katsutoshi Watanabe (Japan Atomic Energy Research Inst., Tokai, Japan.), Hajime Nakajima (Japan Atomic Energy Research Inst., Tokai, Japan.), Teiichiro Saitoh, Tamao Takatsu, Hajime Koikegami, and Makoto Higuchi Jun. 1994 29 p In JAPANESE
(DE95-721871; JAERI-M-94-081-4) Avail: CASI HC A03/MF A01

Tensile properties due to thermal aging on Hastelloy Alloy XR base metals and welded joints were investigated as a series of evaluation tests on the base metals and filler metals for the High Temperature Engineering Test Reactor (HTTR) components. Tensile test in air was performed at R.T. and then same temperatures as the thermal aging temperatures after the specimens were aged at 800, 900, and 1000 C for 1000 hrs. In comparison with the previous data, the present results had no significant difference on the strength characteristics, and were in the previous data band on the ductility. Therefore, it is concluded that these base metals and filler metals for the HTTR components have excellent tensile properties. DOE

HYDROGEN ABSORPTION IN IRON AND STEEL DURING GAS TUNGSTEN ARC WELDING Thesis
J. Hooijmans Nov. 1994 169 p
(PB95-197018; ISBN-90-407-1071-6) Copyright Avail: CASI HC A08/MF A02

This thesis deals with the process of hydrogen absorption during arc welding of iron and steel. Fundamental insight in this process is of vital importance as the hydrogen absorbed by the weld metal can result in serious problems, as described in the foregoing. Understanding of the absorption mechanism will make it possible to indicate in which ways hydrogen absorption can be reduced. NTIS

(DE95-008901; CONF-941144-105) Avail: CASI HC A02/MF A01

The authors have examined the damage produced by Si-ion implantation into strained Si(1-x) Ge(x) epilayers. Damage accumulation in the implanted layers was monitored in situ by time-resolved reflectivity and measured by ion channeling techniques to determine the amorphization threshold in strained Si(1-x)Ge(x) (x = 0.16 and 0.29) over the temperature range 30-110 C. The results are compared with previously reported measurements on unstrained Si(1-x)Ge(x), and with the simple model used to describe those results. They report here data which lend support to this model and which indicate that pre-existing strain does not enhance damage accumulation in the alloy layer. DOE

THE ELECTRODEPOSITION OF LOW CONTRACTION CHROMIUM/MOLYBDENUM ALLOYS USING PULSE-REVERSE PLATING Final Report
Mark D. Miller and Stephen Langston Dec. 1994 18 p
(AD-A292727; ARCCB-TR-94049) Avail: CASI HC A03/MF A01

The use of modulated pulse periodic reverse (pulse-reverse) current to electrodeposit a low contraction (LC) chromium/molybdenum alloy has been evaluated. When using one full pulse-reverse plating cycle, the percent molybdenum in the deposit increased almost 400 percent (from 1 to 4 percent) as the current in the reverse cycle was increased from 0 to 10 amps. However, when the pulse reverse current was carried to six full plating cycles, the percent molybdenum in the deposit was not dependent upon the current and remained constant at about 1 percent. This is about the same percent molybdenum that could be expected in direct current-plated LC chromium/molybdenum alloy and about half the percent molybdenum that could be expected in an on/off pulse-plated LC chromium/molybdenum alloy. LOCALIZATION IN TUNGSTEN HEAVY ALLOYS SUBJECTED TO SHEARING DEFORMATIONS UNDER SUPERIMPOSED HIGH PRESSURES Final Report, Sep. 1991 - Nov. 1994
K. T. Ramesh 27 Feb. 1995 20 p
(Contract DAAL03-91-G-0079)
(AD-A293177; ARO-28272.10-MS) Avail: CASI HC A03/MF A01

This report presents the results of investigations into the deformation and failure of tungsten-based composites (tungsten heavy alloys) at very high strain rates. Several new experimental techniques developed during the course of the work include pressure-shear recovery, allowing the recovery of samples subjected to high-rate shearing deformations; the dynamic measurement of radial strains, and the continuous measurement of projectile velocities. The experimental results showed that the development of adiabatic shear localization in tungsten heavy alloys is influenced by a superimposed hydrostatic pressure. Experimental characterizations have been performed of the very high-rate response of tungsten composites with tungsten-nickel-iron and hafnium matrices. It has been shown that these materials must be treated as dual-phase composites. The addition of a hard particulate reinforcement is shown to result in a substantial increase in matrix rate-sensitivity in a model metal-matrix composite. A simple modeling approach has been developed that allows one to predict the dynamic mechanical properties of a particle-reinforced metal-matrix composite given only the properties of the matrix phase. EFFECT OF LOCAL MELTING ON TRIBOLOGY IN METAL CUTTING
N. Tomac, K. Toennessen, and F. O. Rasch 8 Aug. 1994 14 p Prepared in cooperation with Technical Univ. of Norway, Trondheim; and Narvik Inst. of Tech., Narvik, Norway
(PB95-195392; STF30-S94003) Avail: Issuing Activity (National Technical Information Service (NTIS))

A feature when cutting many types of metals is that workpiece material

adheres to the cutting tool at the sliding contact surfaces between the work material and the tool. The built-up material formed during cutting is of fundamental importance in machining. The paper especially concerns the material build-up at the side flanks of the tool. This type of build-up differs from the more familiar built-up edge (BUE) and is termed 'flank build-up' (FBU). The FBU appears at high cutting speeds in materials like magnesium alloys, nodular cast iron, particle reinforced and cast aluminum alloys with a high content of silicon. Comprehensive machining tests of various magnesium alloys have shown that the presence of the intermetallic Beta-phase is associated with the FBU-formation. In the present paper, a close relationship between the critical cutting speed (temperature) and the amount of Beta-phase in the workpiece material is diagrammatically presented. NTIS

PHYSICAL MODELLING OF MICROSTRUCTURAL EVOLUTION DURING THERMOMECHANICAL PROCESSING OF ALUMINIUM ALLOYS
E. Nes, H. E. Vatne, O. Daaland, T. Furu, and R. Oersund 1994 35 p Prepared in cooperation with Technical Univ. of N orway, Trondheim; and Hydro Aluminum A/S, Karmoy, Norway
(PB95-196341; STF24-S94003) Avail: Issuing Activity (National Technical Information Service (NTIS))

New physically based models for substructure evolution, recrystallization kinetics, grain size and texture after single and multipass hot deformation of aluminum are presented. The approach taken differs from similar models developed for steels. The models discussed here rely on the calculation of the stored energy during deformation and the subsequent recrystallization kinetics and related reaction products such as grain size and texture. Much effort has been directed towards identifying the nature of the nucleation sites for recrystallized grains of different crystallographic orientations. This is essential in order to elevate the model from an empirical to a physical level, the latter being necessary for a good insight into, as well as control of, the rolling process. Particle stimulated nucleation, nucleation from cube bands and grain boundary areas have been incorporated in the model. These concepts are then applied to some examples from commercial production of aluminum sheets. NTIS

MICROSTRUCTURAL AND MECHANICAL PROPERTY CHANGES IN MODEL Fe-Cu ALLOYS
P. M. Rice, R. E. Stoller, B. N. Lucas, and W. C. Oliver (Nano Instruments, Inc., Knoxville, TN.) 1994 7 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-010117; CONF-941144-130) Avail: CASI HC A02/MF A01

This paper describes a technique developed to determine values for the dislocation barrier strength of the defects believed to be responsible for the embrittlement of light water reactor (LWR) pressure vessel steels. Microstructures consisting of a single defect type were introduced by ion irradiation or thermal annealing, and the defect distributions were determined by TEM. Hardness changes were measured using a nano indenter and the dislocation barrier strengths for the defects involved were computed based on a dispersed barrier hardening model. DOE

REVIEW OF ENVIRONMENTAL EFFECTS IN INTERMETALLICS
E. P. George and C. T. Liu 1994 16 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-010120; CONF-941144-131) Avail: CASI HC A03/MF A01

The phenomenology and mechanisms of environmental embrittlement in ordered intermetallics is reviewed by considering two model alloy systems of the L1(sub 2) and B2 crystal classes (Ni3Al and FeAl). Both H2O and H2, at levels found in ordinary ambient air, are found to cause environmental embrittlement, with the former usually more deleterious. In the case of H2O, the micromechanism involves reaction with the intermetallic to form an oxide (or hydroxide) and simultaneous generation of atomic hydrogen which then enters the metal and causes embrittlement. In the case of H2, on the other hand, atomic hydrogen is generated as a result of the dissociation of physisorbed hydrogen molecules on the intermetallic surfaces. Consistent with the proposed embrittlement mechanism, ductility is found to increase with decreasing amounts of H2O (or H2) in the test environment, increasing strain rate, and decreasing (or increasing) temperature. Environmental embrittlement in Ni3Al (and other L1(sub 2) alloys) occurs predominantly intergranularly, whereas in FeAl (and other B2 alloys) it can also occur transgranularly, presumably because diffusion of hydrogen is fast enough through the bulk in the more open B2 structure but only so along grain boundaries in the L1(sub 2) structure. Microalloying with B, which segregates strongly to the grain boundaries, can overcome environmental embrittlement in L1(sub 2) alloys, but not in B2 alloys; in the latter, alloying additions probably have to be added at significantly higher (macroalloy) levels to affect the bulk properties. In neither alloy is environmental embrittlement the sole source of brittleness: depending on the alloy stoichiometry, and grain boundary character, a given grain boundary may be intrinsically weaker (or stronger) than the bulk, thereby influencing overall ductility. DOE

N95-31107# Oak Ridge National Lab., TN.
THE EFFECT OF GRAIN REFINEMENT ON THE ROOM-TEMPERATURE DUCTILITY OF AS-CAST Fe3Al-BASED ALLOYS
S. Viswanathan, V. K. Andleigh, and C. G. McKamey 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-010121; CONF-941144-132) Avail: CASI HC A02/MF A01

Fe3Al-based alloys exhibit poor room temperature ductility in the as-cast condition. The effect of grain refinement of the as-cast alloy on room-temperature ductility was investigated. Small melts of Fe-28 at. % Al-5 at. % Cr were inoculated with various alloying additions and cast into a 50 x 30 x 30-mm graphite mold. The resulting ingots were examined metallographically for evidence of grain refinement, and three-point bend tests were conducted on samples to assess the effect on room-temperature ductility. Ductility was assumed to correlate with the strain corresponding to the maximum stress obtained in the bend test. The results showed that titanium was extremely effective in grain refinement, although it severely embrittled the alloy in contents exceeding 1%. Boron additions strengthened the alloy significantly, while carbon additions reduced both the strength and ductility. The best ductility was found in an alloy containing titanium, boron, and carbon. DOE

SHAPE MEMORY PROPERTIES OF AN IRON MODIFIED NICKEL ALUMINIDE ALLOY
J. A. Horton, C. T. Liu, and E. P. George 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-010223; CONF-941144-128) Avail: CASI HC A02/MF A01

The ordered intermetallic NiAl with aluminum levels near 36% undergoes a B2 to martensite transformation. Shape memory alloys based on NiAl + Fe have the potential for transition temperatures of greater than 150 C. While binary alloys appear inherently brittle, alloying with iron and boron results in two phase alloys with L1(sub 2) and B2 phases and with about 7% room temperature tensile ductility. These alloys show a two-way shape memory effect over a range of transition temperatures with austenite peak temperature, Ap, between 100 to 200 C based on composition. Unfortunately, the B2 phase and its low temperature body centered tetragonal martensitic form are not stable and both can transform to Ni5Al3 with a loss in ductility. These alloys with a constant tensile load show a two way shape recovery of up to 0.6% during temperature cycling between 100 and 200 C. A thorough survey of the shape memory properties of one such alloy with a composition of Ni-25.5 Al-16 Fe-0.12 B (at.%) as a function of prior cold work, tensile loading, and other training steps is presented. Nanoindentation was used to independently measure the mechanical properties of the two phases. DOE

HYDROSTATIC EXTRUSION OF BSCCO/Ag COMPOSITE WIRE
John F. Bingert, Barry L. Bingham, Robert J. Sebring, and Ann M. Kelly 1995 11 p Presented at the Annual Meeting and Exhibition of the Minerals, Metals and Materials Society, Las Vegas, NV, 12-16 Feb. 1995

(Contract W-7405-eng-36)
(DE95-007862; LA-UR-95-654; CONF-950201-9) Avail: CASI HC A03/MF A01

The application of hydrostatic extrusion processing to composite wire fabrication offers several advantages over conventional reduction techniques. These include enhanced uniformity, increased reduction capability, and successful extrusion of normally brittle materials. Specifically, this work involved an experiment to screen the effects of seven extrusion process parameters on the uniformity and density of as-extruded BSCCO-core wire, and the required extrusion pressure. Results suggest the following factors to be potentially significant: (1) back pressure, extrusion ratio, and die angle on core uniformity, (2) packing method, extrusion ratio, silver powder additions, and temperature on density, and (3) extrusion ratio and temperature on extrusion pressure. EFFECT OF COLD WORK ON CREEP PROPERTIES OF HASTELLOY XR
Yuji Kurata (Japan Atomic Energy Research Inst., Tokai, Japan.) and Hajime Nakajima Aug. 1994 37 p In JAPANESE
(DE95-722056; JAERI-Research-94-004) Avail: CASI HC A03/MF A01

Creep tests of Hastelloy XR, in 10%, 20% cold worked or solution treated condition, were made at 800 to 1000 C for times up to about 2000 ks in order to investigate the effect of cold work on creep properties. The results obtained are as follows: (1) Below 950 C, creep rupture strength of 10% cold worked Hastelloy XR is beyond the value of solution treated one within this experimental condition. 950 C and cold work of 10% are the highest values experienced in an intermediate heat exchanger of the High Temperature Engineering Test Reactor (HTTR) under normal condition, respectively. (2) At 800 and 850 C, creep rupture time of 20% cold worked Hastelloy XR is longer than that of solution treated one. However, the effect disappears above 900 C. At 950 and 1000 C, it becomes shorter than that of solution treated Hastelloy XR. (3) Rupture elongation and reduction of area of cold worked Hastelloy XR are smaller than those of solution treated one. While these values of 10% or 20% cold worked material are lowest at 900 C, they recover considerably at 1000 C. (4) Minimum creep rate, epsilon-dot (sub m), of 10% or 20% cold worked Hastelloy XR is decreased by as much as a factor of 20 to 50 at 800 to 900 C. On the other hand, epsilon-dot (sub m) of 10% or 20% cold worked material is increased at 1000 C. (5) From the results of microstructure observation of ruptured specimens, decrease in creep rupture strength of cold worked Hastelloy XR is interpreted in terms of extensive recrystallization which occurs during creep at 1000 C. EFFECT OF IRRADIATION SPECTRUM ON THE MICROSTRUCTURE OF ION-IRRADIATED Al2O3
S. J. Zinkle 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-010225; CONF-941144-126) Avail: CASI HC A02/MF A01

Polycrystalline samples of alpha-alumina have been irradiated with various ions ranging from 3.6 MeV Fe(+) to 1 MeV H(+) ions at 650 C. Cross-section transmission electron microscopy was used to investigate the depth-dependent microstructure of the irradiated specimens. The microstructure following irradiation was observed to be dependent on the irradiation spectrum. In particular, defect cluster nucleation was effectively suppressed in specimens irradiated with light ions such as 1 MeV H(+) ions. On the other hand, light ion irradiation tended to accelerate the growth rate of dislocation loops. The microstructural observations are discussed in terms of ionization enhanced diffusion processes. OBSERVATIONS OF STAR FRACTURE AND LONGITUDINAL SPLITTING IN BIS 812 EMA AND Q1N SUBMARINE CONSTRUCTION STEELS
I. A. Burch and David S. Saunders Mar. 1995 31 p
(DSTO-RR-0014; AR-008-963) Avail: Issuing Activity (DSTO Aeronautical and Maritime Research Lab., GPO Box 4331, Melbourne, Victoria 3001, Australia)

The tensile properties and fracture behavior of two submarine construction steels, BIS 812 EMA and Q1N, have been studied. Their properties and fracture behavior were measured over a wide range of test temperatures utilizing plain and notched tensile specimens. The yield strength of both materials was found to increase with decreasing temperature and the fracture surface appearance of these steels was also temperature dependent. Under certain conditions 'star fracture' was exhibited, rather than the usual cup-and-cone type fracture. The predominance of the 'star type fracture' increased with decreasing temperature in both plain and notched tensile specimens, however, it was suppressed by notching. This paper describes in detail the fractographic features of the surfaces and proposes that a range of conditions exist under which 'star fracture' occurs in these materials. Author

Sandia National Laboratories has established a Cooperative Research and Development Agreement with consortium members of the National Center for Manufacturing Sciences (NCMS) to develop fundamental generic technology in the area of printed wiring board materials and surface finishes. Improved solderability of copper substrates is an important component of the Sandia-NCMS program. The authors are investigating the effects of surface roughness on the wettability and solderability behavior of several different types of copper board finishes. In this paper, the authors present roughness and solderability characterizations for a variety of chemically-etched copper substrates. Initial testing on six chemical etches demonstrate that surface roughness can be greatly enhanced through

chemical etching. Noticeable improvements in solder wettability were observed to accompany increases in roughness. A number of different algorithms and measures of roughness were used to gain insight into surface morphologies that lead to improved solderability. DOE

COMPARISON OF CATHODIC PROTECTION CURRENTS ON 70/30 COPPER-NICKEL AND ALLOY 625 PIPING SYSTEMS Final Report

Harvey P. Hack and Walter L. Wheatfall Mar. 1995 25 p Limited Reproducibility: Document partially illegible

(AD-A292953; CARDIVNSWC-TR-61-94/14) Avail: CASI HC A03/MF A01

The objective of this study was to determine whether the demand on a cathodic protection system changes when the protected pipe material is changed from copper-nickel to alloy 625. Two piping mockups were designed to simulate a probable geometry for a cathodically protected piping system. Each mockup consisted of a 20-ft (610-cm) length of nominal 2-in.- (5-cm-) diameter piping with a zinc anode for cathodic protection inserted in the discharge end of each. One mockup was made with 70/30 copper-nickel pipe and the other with alloy 625 pipe. Protection currents and potential profiles inside the pipes were measured over a 6-month exposure period in natural seawater flowing at 7 ft/s (210 cm/s). The total protection current and sacrificial anode consumption for alloy 625 pipe were half that for copper-nickel pipe. Thus, replacing copper-nickel pipe with alloy 625 pipe in areas close to cathodically protected heat exchangers or hulls will result in less demand on the cathodic protection system, as opposed to the original copper-nickel piping. HOT COMPRESSION TESTING OF TUNGSTEN

M. G. Vassilaros Mar. 1995 67 p

(AD-A293683; CARDIVNSWC-TR-61-94/17) Avail: CASI HC A04/MF A01

A study of the high temperature deformation behavior of tungsten was performed. The cylindrical specimen dimensions were 0.4 inch diameter and 0.6 inch long (10.2 x 15.2 mm) as machined from a tungsten forging. The compression tests were performed in a thermal-mechanical simulator 'Gleeble 1500' at temperatures of 600 to 3000 F (315 to 1650 C). The specimens were deformed to a strain of approximately 0.3 with lubricated test fixtures that suppressed any specimen barreling. Compressive stress - strain curves were produced for all specimens and analyzed for 0.2% offset strength as well as 1.0, 2.0 and 5.0% offset strengths. The strengths were observed to decrease with higher temperatures, but appeared to be on a plateau at 50 ksi (345 MPa) in the temperature range of 1200 to 2200 F (650 to 1200 C) . The compression specimens tested at or below 10000 F (538 C) experienced cracking. The fracture mode appeared to be intergranular in a single phase microstructure with an elongated grain shape. DTIC

MODELING OF STRESS DISTRIBUTIONS ON THE MICROSTRUCTURAL LEVEL IN ALLOY 600

K. J. Kozaczek, B. G. Petrovic (Pennsylvania State Univ., University Park, PA.), C. O. Ruud (Pennsylvania State Univ., University Park, PA.), and A. R. McIlree (Electric Power Research Inst., Palo Alto, CA.) 1995 10 p Presented at the Joint ASME/JSME Pressure Vessels and Piping Conference, Honolulu, HI, 23-27 Jul. 1995

(Contract DE-AC05-84OR-21400)

(DE95-009135; CONF-950740-18) Avail: CASI HC A02/MF A01

Stress distribution in a random polycrystalline material (Alloy 600) was studied using a topologically correct microstructural model. Distributions of von Mises and hydrostatic stresses at the grain vertices, which could be important in intergranular stress corrosion cracking, were analyzed as functions of microstructure, grain orientations and loading conditions. Grain size, shape, and orientation had a more pronounced effect on stress distribution than loading conditions. At grain vertices the stress concentration factor was higher for hydrostatic stress (1.7) than for von Mises stress (1.5). The stress/strain distribution in the volume (grain interiors) is a normal distribution and does not depend on the location of the studied material volume i.e., surface vs/bulk. The analysis of stress distribution in the volume showed the von Mises stress concentration of 1.75 and stress concentration of 2.2 for the hydrostatic pressure. The observed stress concentration is high enough to cause localized plastic microdeformation, even when the polycrystalline aggregate is in the macroscopic elastic regime. Modeling of stresses and strains in polycrystalline materials can identify the microstructures (grain size distributions, texture) intrinsically susceptible to stress/strain concentrations and justify the correctness of applied stress state during the stress corrosion cracking tests. Also, it supplies the

information necessary to formulate the local failure criteria and interpret of nondestructive stress measurements. DOE

INFLUENCE OF STRAIN RATE AND TEMPERATURE ON THE MECHANICAL BEHAVIOR OF IRON ALUMINIDE-BASED ALLOYS
G. T. Gray 1995 5 p Presented at the Plasticity and Its Current Applications Symposium, Osaka, Japan, 17-21 Jul. 1995
(Contract W-7405-eng-36)
(DE95-009426; LA-UR-95-918; CONF-9507100-1) Avail: CASI HC A01/MF A01

Iron aluminides are receiving increasing attention as potential high temperature structural materials due to their excellent oxidation and sulfidation resistance. Although the influence of strain rate on the microstructure/property relationships of pure iron and a variety of iron alloys and steels has been extensively studied, the effect of strain rate on the stress-strain and deformation response of iron aluminides remains poorly understood. In this paper the influence of strain rate, varied between 0.001 and 10(exp 4)/ sec, and temperature, between 77 & 1073 K, on the mechanical behavior of Fe-40Al-0.1B and Fe-16.12Al-5.44-Cr-0.11Zr-0.13C-1.07Mo-006Y, called FAP-Y, (both in at. percent) is presented. The rate sensitivity and work hardening of Fe-40Al and the disordered alloy based on Fe-16 percent Al are discussed as a function of strain rate and temperature. DOE

INITIAL SURVEY ON FRACTURE TOUGHNESS OF COMMERCIAL Nd2Fe14B
J. A. Horton and J. H. Schneibel 1994 4 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-009813; CONF-941144-138) Avail: CASI HC A01/MF A01

Nd2Fe14B is currently the best (highest energy product) hard magnet available. Like most magnetic materials, it is rather brittle. The fracture toughness of specimens of commercially available Nd2Fe14B magnets were measured us ing a chevron notch three point bend test. Values ranged from nearly 2 to 5.5 MPa(radical)m. Consistent differences were found between the five different types of materials tested. In this initial survey, insufficient tests were done for good statistics to be obtained. However, it appears that this test will allow differences in fracture toughness between alloys with different compositions and fabricated by different production methods to be measured and tracked as improvements are made. A STUDY OF SWITCHING BEHAVIOR IN Pb(Zr,Ti)O3 THIN FILMS USING X-RAY DIFFRACTION
M. O. Eatough, D. Dimos, B. A. Tuttle, W. L. Warren, and R. Ramesh (Bell Communications Research, Inc., Red Bank, NJ.) 1995 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-010859; SAND-95-0761C; CONF-941144-145) Avail: CASI HC A02/MF A01

Pb(Zr,Ti)O3 (PZT) thin films are being developed for use in optical and electronic memory devices. To study ferroelectric switching behavior, the authors have produced relatively untextured PZT thin films on Si substrates. They have developed a method for using x-ray diffraction to observe domain switching in situ. This study involved the use of a micro-diffractometer to monitor the switching behavior in relatively small (0.7 mm diameter) electroded areas. Diffraction analyses were done while DC voltages were applied and removed, representing several places in the hysteresis loop. In particular, the authors were looking for relative intensity changes in the (h00),(001) diffraction peaks as a function of position in the hysteresis loop. This study indicates that the 90 deg domain switching exhibited by bulk ferroelectrics is very limited in films on Si when grain sizes are less than about 1 micron. DOE

MODELING OF GRAIN BOUNDARY STRESSES IN ALLOY 600
K. J. Kozaczek, A. Sinharoy (Pennsylvania State Univ., University Park, PA.), C. O. Ruud (Pennsylvania State Univ., University Park, PA.), and A. R. McIlree (Electric Research and Management, Inc., State College, PA.) 1995 9 p Presented at the Joint ASME/JSME Pressure Vessels and Piping Conference, Honolulu, HI, 23-27 Jul. 1995
(Contract DE-AC05-84OR-21400)
(DE95-009033; CONF-950740-19) Avail: CASI HC A02/MF A01

Corrosive environments combined with high stress levels and susceptible microstructures can cause intergranular stress corrosion cracking (IGSCC) of Alloy 600 components on both primary and secondary sides of pressurized water reactors. One factor affecting the IGSCC is intergranular carbide precipitation controlled by heat treatment of Alloy 600. This study is concerned with analysis of elastic stress fields in vicinity of M7C3 and M23C6 carbides precipitated in the matrix and at a grain boundary triple point. The local stress concentration which can lead to IGSCC initiation was studied using a two-dimensional finite element model. The intergranular precipitates are more effective stress raisers than the intragranular precipitates. The combination of the elastic property mismatch and the precipitate shape can result in a local stress field substantially different than the macroscopic stress. The maximum local stresses in the vicinity of the intergranular precipitate were almost twice as high as the applied stress. DOE

THE INFLUENCE OF MATRIX MICROSTRUCTURE AND TEMPERATURE ON CYCLIC DEFORMATION AND FATIGUE OF PARTICLE-REINFORCED 2219 ALUMINUM Ph.D. Thesis
Gregory Michael Vyletel 1994 171 p
Avail: Univ. Microfilms Order No. DA9423338

Room temperature and elevated temperature (150 C) fatigue studies were conducted on naturally aged, peak-aged, and overaged 2219/TiC/ISp and 2219 Al. In addition, the grain size of 2219/TiC/15p was altered from 35 micrometers to 276 micrometers in an attempt to understand how grain size influences the room temperature and elevated temperature cyclic deformation and fatigue life behavior. Plastic strain-controlled testing was used to study the low-cycle fatigue and cyclic response behaviors while stress-controlled testing was used to investigate the high cycle fatigue behavior. The cyclic response and dislocation microstructures of both reinforced and unreinforced materials were very similar for comparable microstructures. Naturally aged materials showed evidence of cyclic hardening, and in some cases, cyclic softening, while the cyclic response of peak-aged and overaged materials showed no evidence of cyclic hardening or softening (except for overaged 2219 Al at high plastic strain amplitudes). Decreasing grain size was found to modestly increase the cyclic flow stress of 2219/TiC/15p while providing very little improvement in the fatigue-life behavior. The addition of TiC reinforcement was found to improve the stress-controlled fatigue life provided processing defects (i.e., intermetallics and particle clusters) were kept low; however, the plastic strain-controlled fatigue life of the composite was inferior to that of the unreinforced material. At 150 C, cyclic softening was observed at all plastic strain amplitudes for the composite materials and at plastic strain amplitudes greater than approximately 2.5 x 10(exp -3) for the unreinforced materials. This softening was attributed to the decomposition of the theta' strengthening precipitates to the equilibrium theta precipitates. This (theta') decomposition occurred in all materials; however, the combination of cyclic deformation and the presence of reinforcing TiC particles appeared to greatly increase the kinetics, or rate of decomposition. Grain size did not appear to have any significant effect on the extent of the decomposition or the degree of cyclic softening. Dissert. Abstr.

THE INFLUENCE OF MICROSTRUCTURE ON CREEP DEFORMATION IN NEAR-GAMMA TiAl ALLOYS Ph.D. Thesis
Brian Daly Worth 1994 151 p
Avail: Univ. Microfilms Order No. DA9423350

The influence of microstructure on creep deformation has been examined in the near-gamma TiAl alloys Ti-49Al-1V and Ti-48Al-1V-0.3C between 760 C and 870 C in the stress range of 50 MPa to 200 MPa. A systematic approach was made to develop methods to control microstructural morphologies and alpha(sub 2) volume fraction has been conducted. By carefully controlling thermo-mechanical processing parameters, the influence of solution temperature, cooling rate, and secondary heat treatment on volume fraction and morphology of alpha(sub 2) has been determined. Microstructure was shown to have a significant influence on the creep

behavior of the near-gamma TiAl alloy Ti-49Al-1V, with a fully lamellar having the highest creep resistance. Overall creep resistance was by the volume fraction of lamellar constituent, with the lowest creep resistance observed at intermediate lamellar volume fractions. The decrease in creep resistance of the duplex microstructure, compared to the near-gamma microstructure can be explained by an increase in dislocation mobility within the equiaxed gamma constituent. The high creep resistance of the fully lamellar microstructure is attributed to the fine spacing of the lamellar structure, which results in a decreased effective slip length for dislocation motion. The influence of interstitial strengthening and microstructure on creep deformation has been examined in the near-gamma TiAl alloy Ti-48Al-1V-0.3C. Significant improvement in creep resistance was observed in this alloy compared with the Ti-49Al-1V alloy containing low levels of carbon (0.07 at percent). The degree of strengthening resulting from the addition of carbon was greater in the near-gamma and duplex microstructures than in the fully lamellar microstructure. A decrease in stress exponent from 4 to 3 occurs and the formation of sub-boundaries is inhibited with the addition of carbon in both the duplex microstructure and near-gamma microstructures. These findings suggest that solute/dislocation interaction mechanisms are responsible for the significant increase in creep resistance observed in this alloy with the addition of carbon. Dissert. Abstr.

A STUDY OF DAMASCUS STEEL Ph.D. Thesis
P. Berge 16 Feb. 1995 77 p
(Contract W-7405-eng-82)
(DE95-010127; IS-T-1703) Avail: CASI HC A05/MF A01

The Damascus sword has been an article of fascination for many years to blade collectors and metallurgists alike. The blades were given their name by Europeans who encountered these blades which originated from Damascus, Syria. They are best known for the appearance of the blade face. Genuine Damascus blades show swirling patterns of alternating light and dark regions which are due to the microstructure of the steel. The microstructure consists of arrays of well rounded cementite patterns in a matrix of either pearlite, bainite, or martensite. When this structure is etched the matrix will turn dark leaving the cementite particles light. Although many blades were produced over the centuries, while some of the process is known the making of a genuine Damascus blade today is generally considered a lost art. Many scientists have studied the subject in an attempt to understand the complex process by which the clustered arrays of cementite particles develop in the steel blades. The most prominent theories to date are presented in the General Introduction to this thesis. The thesis is divided into four main parts. In the first part, four proposed mechanisms of cementite cluster sheet formation as they relate to the banding theory are introduced. Experiments to investigate these mechanisms are presented. In Part 2, collaborative research focused on the methodology of the reconstructed process for making Damascus steel is presented. In the third part, a study into the graphitization of the reconstructed blades is presented. In Part 4, experimental attempts at producing Damascus steel ingots in the laboratory are presented. DOE

SYNTHESIS AND CHARACTERIZATION OF NANOPHASE FACE-CENTERED-CUBIC TITANIUM
Alan F. Jankowski and Mark A. Wall Feb. 1995 6 p Presented at the Annual Meeting and Exhibition of the Minerals, Metals and Materials Society (TMS), Las Vegas, NV, 12-16 Feb. 1995
(Contract W-7405-eng-48)
(DE95-009533; UCRL-JC-119682; CONF-950201-10) Avail: CASI HC A02/MF A01

Unalloyed Ti is sputter deposited in the formation of two trilayer films. Each layer within the combinations of Ni-Ti-Ni and Ti-Ni-Ti is less than 0.1 micro m thick. High resolution imaging and electron diffraction results are presented for the microstructural characterization of both trilayer films. Nanophase fcc Ti is initially found in crystalline layers grown on Ni whereas hcp Ti is found in layers grown without a Ni epilayer. Conditions are further examined under which the fcc to hcp transition occurs for Ti deposited on Ni. DOE

INTERFACIAL SEGREGATION AND DEFORMATION OF SUPERPLASTICALLY DEFORMED Al-Mg-Mn ALLOYS
John S. Vetrano, Curt A. Lavender, and Stephen M. Bruemmer Mar. 1995 9 p Presented at the Annual Meeting and Exhibition of the Minerals, Metals and Materials Society (TMS), Las Vegas, NV, 12-16 Feb. 1995
(Contract DE-AC06-76RL-01830)
(DE95-009572; PNL-SA-26013; CONF-950201-13) Avail: CASI HC A02/MF A01

Microstructural and microchemical studies have been carried out on superplastically deformed Al-Mg-Mn (AA5083-type) alloys. Grain boundary composition was measured using a Scanning Auger Microprobe (SAM) and an Analytical Transmission Electron Microscope (ATEM), while conventional TEM was used for microstructural evaluation. Non-equilibrium segregation of Si to grain boundaries following deformation was measured by both techniques. Significant interfacial Si enrichment was only detected in gage sections of tensile specimens after uniaxial strains from 50 to 200%. Grip regions which experience identical thermal histories, but without plastic deformation, did not reveal Si segregation. Selected samples also showed a slight depletion of Mg at grain boundaries after deformation. The only reproducible observation of equilibrium segregation was in Zr-modified alloys, where Sn was detected by SAM in both the deformed and undeformed sections of the sample. Microstructural analysis documented subgrain formation and subgrain-precipitate interactions during superplastic deformation. In addition, many grain boundaries and precipitate interfaces contained small (5 to 20 nm) voids. Compositional analysis of these nano-voids revealed that they were enriched in Mg with the adjacent boundary regions correspondingly depleted. DOE

ROBOTIC WELD OVERLAY COATINGS FOR EROSION CONTROL Quarterly Technical Progress Report, Oct. 1994 - Dec. 1994
B. F. Levin, J. N. Dupont, and A. R. Marder 25 Jan. 1995 17 p
(Contract DE-FG22-92PC-92542)
(DE95-009643; DOE/PC-92542/T9) Avail: CASI HC A03/MF A01

Research is presently being conducted to develop a criteria for selecting weld overlay coatings for erosion mitigation in Circulated Fluidized Beds. Initially, eleven weld overlay alloys were selected for erosion testing based upon a literature review. All eleven coatings were deposited on 1018 steel substrates using the plasma arc welding process. Ten samples from each coating were prepared for erosion testing. The coating deposition and sample preparation procedures were described in the second quarterly report. All selected coatings were erosion tested at 400 C and their erosion resistance was evaluated by determining the steady state erosion rate. In addition, the microstructure of each coating was characterized before and after the erosion tests. The results of the tests are discussed in the third quarterly report. No correlations were found between room temperature hardness of the weld overlay coatings and their erosion resistance at elevated temperature. During the last quarter tensile tests were performed at 400 C for the Ultimet, Inconel-625, 316L SS, C-22, and Stellite-6 wrought alloys. The erosion tests for these materials at 400 C are in progress. The results of mechanical and erosion tests will be used to correlate mechanical properties of selected wrought alloys such as tensile toughness, ductility, strain hardening coefficient and yield strength to their erosion resistance at 400 C. Also, the erosion behavior of the wrought alloys compared with similar weld alloys will be analyzed. The experimental procedure and results of the tensile tests are presented in this progress report. CASCADE DAMAGE IN THE ORDERED ALLOY Ni3Al
T. X. Bui, I. M. Robertson, and M. A. Kirk (Argonne National Lab., IL.) Jan. 1995 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contracts DE-FG02-91ER-45439; W-31-109-eng-38)
(DE95-009893; ANL/MSD/CP-85468; CONF-941144-134) Avail: CASI HC A02/MF A01

The damage (disordered zones and vacancy loops) produced in the ordered alloy Ni3Al by irradiation with different ions (Ar(+), Kr(+), Xe(+)), ion energies (30 and 50 keV), and at 30 and 300 K has been investigated by using transmission electron microscopy. At room temperature and at constant ion energy, the average size of the disordered zones increases

as the ion mass increases from Ar(+) to Kr(+) and to Xe(+) ions. This trend is opposite to that of the collisional volume which decreases with increasing ion mass and highlights the importance of the thermal spike in causing disorder. At room temperature and at constant ion mass, the zone size increases with increasing ion energy. At 30 K, for the same ion mass and ion energy, the size of the disordered zones is smaller than at room temperature. At both irradiation temperatures, the dislocation loop yield increases with increasing ion energy and ion mass. The loop yield was lower for irradiations at 30 K compared to at 300 K. Comparison of the dislocation loop yield and the size of the disordered zones indicates that the probability for forming a loop increases with the size of the disordered zone. DOE

COMPREHENSIVE RESEARCH ON THE STABILITY AND ELECTRONIC PROPERTIES OF a-Si:H AND a-SiGe:H ALLOYS AND DEVICES Final Subcontract Report, 10 Mar. 1991 - 30 Aug. 1994
V. Dalal (Iowa State Univ. of Science and Technology, Ames, IA.) Apr. 1995 108 p
(Contract DE-AC36-83CH-10093)
(DE95-004088; NREL/TP-411-7695) Avail: CASI HC A06/MF A02

This report describes work on the growth of a-Si:H and a-(Si,Ge):H materials and devices using well-controlled growth techniques. The a-Si:H materials were grown at higher temperatures (300-375 C) using electron-cyclotron-resonance (ECR) plasma techniques with a remote H beam. These films have excellent electronic quality and show significant improvements in stability compared with glow-discharge-produced a-Si:H materials. Several problems were encountered during the fabrication of devices in these materials, and we were able to overcome them by a systematic work on buffer layers in these cells. We also studied alternative designs for improving the stability of a-Si:H cells and produced graded-gap a-Si:H cells using glow-discharge that are more stable than comparable standard, ungraded glow discharge devices. Finally, systematic work was done to produce good-quality a-(Si,Ge):H films, using triode radio frequency (RF) glow-discharge with ion bombardment during growth. Diagnostic devices were made using these films, and the properties of the material, such as Urbach energies and hole mobility-lifetime products, were measured in these devices. We found a systematic increase in the Urbach energies, and a corresponding decrease in the hole and electron mu tau products, as the Ge content of the alloys increases. DOE

MINUTES OF THE FOURTH ANNUAL WORKSHOP ON CHROMATE REPLACEMENTS IN LIGHT METAL FINISHING
T. R. Guilinger, R. G. Buchheit, C. Drewien, L. M. Maestas, K. R. Zavadil, G. Bierwagen (North Dakota State Univ., Fargo, ND.), M. Kendig (Rockwell International Science Center, Palo Alto, CA.), R. Rungta (General Motors Corp., Anderson, IN.), and L. Vega (Aluminum Co. of America, Alcoa Center, PA.) Apr. 1995 160 p Presented at the 4th Annual Workshop on Chromate Replacements in Light Metal Finishing, Albuquerque, NM, 18-19 Aug. 1994
(Contract DE-AC04-94AL-85000)
(DE95-010937; SAND-94-3010; CONF-9408156) Avail: CASI HC A08/MF A02

The purpose of publishing the minutes of this workshop is to document the content of the presentations and the direction of the discussions at the workshop as a means of fostering collaborative research and development on chromate replacements throughout the defense, automotive, aerospace, and packaging industries. The goal of the workshop was to bring together coating researchers, developers, and users from a variety of industries to discuss new coating ideas, testing methods, and coating preparation techniques from the perspective not only of end user, but also from the perspective of coating supplier, developer, and researcher. To this end, we succeeded because of the wide-ranging interests of attendees present in the more than 60 workshop registrants. It is our hope that future workshops, not only this one but others like it throughout government and industry, can benefit from the recorded minutes of our meeting and use them as a starting point for future discussions of the directions for chromate replacements in light metal finishing. INFLUENCE OF LAYER ORDER AND COMPOSITION ON THE MAGNETIC ANISOTROPY OF ULTRA-THIN Co SANDWICHES
B. N. Engel, C. Marliere, and C. M. Falco 1994 3 p Presented at the 14th International Colloquium on Magnetic Films and Surfaces, Duesseldorf, Germany, 29 Aug. - 2 Sep. 1994
(Contract DE-FG03-93ER-45488)
(DE95-010608; DOE/ER-45488/1; CONF-940829-2) Avail: CASI HC A01/MF A01

In situ polar Kerr effect measurements have been used to study the magnetic anisotropy of molecular beam epitaxially (MBE)-grown X/Co/Y sandwich structures, where X and Y are each one of the nonmagnetic metals Ag, Au, Cu, or Pd. This lead to the discovery, reported earlier, that the magnitude of the X/Co/Y perpendicular anisotropy is strongly peaked at approximately 1 atomic layer overlayer coverage. Reported here are extensions of this work to investigate the influence of layering order and overlayer composition on this anomalous anisotropy behavior. Measurements to date indicate that the peak in perpendicular anisotropy is present regardless of layer order, i.e. X/Co/Y or Y/Co/X. However, layer-order-dependent behavior is found when the overlayer material is changed after initial coverage, i.e. X/Co/Y/X. Derived from text

CREEP OF A FINE-GRAINED, FULLY-LAMELLAR, TWO-PHASE TiAl ALLOY AT 760 C
J. N. Wang, A. J. Schwartz, T. G. Nieh, C. T. Liu, V. K. Sikka, and D. Clemens (Pratt and Whitney Aircraft, Jupiter, FL.) Feb. 1995 9 p Presented at the Annual Meeting and Exhibition of the Minerals, Metals and Materials Society (TMS), Las Vegas, NV, 12-16 Feb. 1995
(Contracts W-7405-eng-48; DE-AC05-84OR-21400)
(DE95-009531; UCRL-JC-119681; CONF-950201-11) Avail: CASI HC A02/MF A01

Creep of a TiAl alloy, having a composition of Ti-47Al-2Cr-2Nb (in atom %) and a fine-grained, fully-lamellar structure, was carried out at 760 C and stresses between 69-723 MPa. It was found that, in addition to having good room temperature properties, the alloy exhibits higher creep resistance than other TiAl alloys with a similar composition. Both the creep data and microstructures of the alloy suggest that there exists a change in deformation mechanism from a glide-controlled process at high stresses to a recovery-controlled process at low stresses. Also, microstructural evidence indicates that the rate-controlling recovery mechanism is the climb of dislocation segments pinned by ledges at gamma/alpha(sub 2) interfacial boundaries. DOE

Parameter-free electronic structure approaches are now being used to predict chemical order and, to a lesser extent, structural transformations in multicomponent alloys, as a function of temperature, concentration, and pressure. The underlying state-of-the-art framework is briefly reviewed, and applications to specific aspects of the statics and kinetics of alloy

transformations are discussed. Finally special emphasis is put on the relations between stability and mechanical properties in substitutional alloys with examples pertaining to the energetics of antiphase boundaries and interfaces. DOE

Sol-gel processing has been widely used in the preparation of lead zirconate titanate (PZT) thin films. The authors have applied this methodology to the formation of lead magnesium niobate (PMN) spin-cast deposited thin films. Since there is a limited number of soluble, commercially available compounds, the authors have recently synthesized a series of novel metal alkoxides for use as precursors for generation of PMN thin films and powders. The process for generation of the perovskite phase of these PMN powders and films are reported. DOE

EPOXY AND ACRYLATE STEREOLITHOGRAPHY RESINS: IN-SITU MEASUREMENTS OF CURE SHRINKAGE AND STRESS RELAXATION
T. R. Guess, R. S. Chambers, T. D. Hinnerichs, G. D. McCarty, and R. N. Shagam 1995 14 p Presented at the 6th International Conference on Rapid Prototyping, Dayton, OH, 4-6 Jun. 1995
(Contract DE-AC04-94AL-85000)
(DE95-008506; SAND-94-2569C; CONF-9506149-1) Avail: CASI HC A03/MF A01

Techniques were developed to make in situ measurements of gelled resin to determine linear shrinkage, stress-strain response and stress relaxation of single strands of SL 5170 epoxy and SL 5149 photocurable resins. Epoxy strands shrank approximately 1.4% and the acrylate strands about 1.0% after a single exposure. No forces were measured during cure shrinkage of strands following the first laser exposure. In multiple laser exposures, the acrylate continues to shrink; whereas (University of Dayton data) no additional shrinkage is observed in epoxy strands on a second hit. In force relaxation tests, a strand is drawn and then a 0.5% step strain is applied after different elapsed times. The epoxy initial modulus evolves (increases) with elapsed time following draw of the strand, and this evolution in modulus occurs after linear shrinkage has stopped. On the other hand, acrylates show no evolution of modulus with elapsed time following a single laser draw; i.e., once shrinkage stops after one laser hit, the initial modulus remains stable with elapsed time. Finally, relaxation response times of epoxy strands get larger with increasing elapsed time after laser draw. In acrylate strands there was no evolution in initial modulus with elapsed time after a single draw so relaxation times are not a function of elapsed time after a single hit with the laser. DOE

PROCESS FOR PRODUCING HYDROPHILIC POLYMER MEMBRANES Patent
Barbara F. Howell, inventor (to Navy), Ravanasamudram S. Venkatachalam, inventor (to Navy), and John P. Wehrle, inventor (to Navy) 18 Oct. 1994 5 p Filed 28 Sep. 1993
(AD-D017355; US-Patent-5,356,936; US-Patent-Appl-SN-128289) Avail: US Patent and Trademark Office

Hydrophilicity of hydrophilic polymers, in the form of heat-crosslinked coatings on porous membranes, is increased by exposure to an oxygen plasma, preferable for about 60 seconds. The plasma is generated at an oxygen gas pressure of about 1.5 Torrs in a chamber subjected to radio frequency electromagnetic radiation with a power of 25-100 watts. Such highly hydrophilic membranes have increased efficiency and durability when used as ultrafiltration membranes for separating hydrophobic and hydrophilic materials, such as smoke-air and oil-water mixtures. ORIENTATION OF RAPID THERMALLY ANNEALED LEAD ZIRCONATE TITANATE THIN FILMS ON (111) Pt SUBSTRATE
K. G. Brooks, I. M. Reaney, R. Klissurska, Y. Huang, L. A. Bursill, and N. Setter 1994 45 p
(DE95-615232; UM-P-94/39) Avail: CASI HC A03/MF A01 (US Sales Only)

The nucleation, growth and orientation of lead zirconate titanate thin films prepared from organometallic precursor solutions by spin coating on (111) oriented platinum substrates and crystallized by rapid thermal annealing was investigated. The effects of pyrolysis temperature, post-pyrolysis thermal treatments, excess lead addition, and Nb dopant substitution are reported. The use of post pyrolysis oxygen anneals at temperatures in the regime of 350-450 C was found to strongly effect the kinetics of subsequent amorphous-pyrochlore perovskite crystallization by rapid thermal annealing. It has also allowed films of reproducible microstructure and textures (both (100) and (111)) to be prepared by rapid thermal annealing. It is suggested that such anneals and pyrolysis temperature affect the oxygen concentration/average Pb valence in the amorphous films prior to annealing. The changes in Pb valence state then affect the stability of the transient pyrochlore phase and thus the kinetics of perovskite crystallization. Nb dopant was also found to influence the crystallization kinetics. DOE

SYNTHESIS OF CARBO-NITRIDE FILMS USING HIGH-ENERGY SHOCK PLASMA DEPOSITION
V. N. Gurarie, A. V. Orlov, K. W. Nugent, P. Weiser, and S. Prawer 1994 6 p
(DE95-615231; UM-P-94/27) Avail: CASI HC A02/MF A01 (US Sales Only)

Recent investigations shows that an enhanced nitrogen content of carbo-nitride films improves wear resistance, hardness, tribological and other properties of these films. The present work reports on the properties of nitrogen rich carbon films produced by an intense gas discharge between carbon electrodes in a nitrogen atmosphere. The energy of the discharge, initial nitrogen pressure, number of discharges and geometry are varied to establish their effect on the nitrogen content and the mechanical, structural and morphological characteristics of the deposited carbon-nitride films. The structural diagnostics include optical and scanning electron microscopy, as well as Auger and Raman Spectroscopes and Rutherford Backscattering. The C-N films formed fell into two categories, differing in morphology and mechanical properties. Type I are C-N films, containing up to 35 at. % nitrogen, and which have an amorphous structure. These films are formed at relatively low plasma shock pressure and exhibit relatively low microhardness, approximately 2 GPa. In a relatively narrow range of the plasma shock pressure and temperature the second type of C-N deposition is observed consisting of high density, closely-packed crystal-like grains growing perpendicular to the substrate surface and displaying a cauliflower-like morphology. The microhardness of these films reaches 15 GPa, as measured by the Vickers method. DOE

ION IMPLANTATION AND THERMAL STRESS RESISTANCE OF CERAMICS
V. N. Gurarie, J. S. Wiliams, and A. J. Watt 1994 15 p
(DE95-615349; UM-P-93/93) Avail: CASI HC A03/MF A01 (US Sales Only)

Monocrystals of sapphire and magnesia together with glass samples have been subjected to ion implantation prior to thermal shock testing in a plasma of continuously varied intensity. Measurements of the gap between adjacent fragments have been used to estimate the surface temperature. Fracture and deformation characteristics of the surface layer are measured in ion implanted and unimplanted samples using optical and scanning electron microscopy. Ion implantation is shown to modify the near-surface structure of ceramic samples by introducing damage, which makes crack initiation easier under thermal stresses in sapphire and magnesia crystals. The fracture threshold and maximum crack density are shifted towards the lower temperature range. Ion implanted MgO crystals show a ten fold increase in surface crack density. An increased crack density results in a decreased degree of damage characterized by the depth of crack penetration. The thermal stress resistance parameter of glass samples is increased at relatively small doses and decreased at higher doses. The results suggest that crack density and the degree of fracture damage in brittle ceramics operating under thermal shock conditions can be effectively controlled by ion implantation which provides crack initiating defects in the near-surface region. ELECTROCHEMICAL VAPOUR DEPOSITION OF SOFC INTERCONNECTION MATERIALS Ph.D. Thesis
V. vanDieten 23 Jan. 1995 206 p
(PB95-197844; ISBN-90-407-1075-9) Avail: CASI HC A10/MF A03

The aim of this thesis is to investigate the synthesis of the SOFC (Solid Oxide Fuel Cells) interconnection material Mg-doped LaCrO3 by means of EVD (electrochemical vapor deposition). Although the EVD process is the key technology for the fabrication of the interconnect of the Westinghouse tubular concept SOFC, very little has been published on this subject. Nearly all publications on EVD are dealing with the synthesis of the electrolyte material YSZ. In Chapter 2 the principle of the EVD process is described, as well as the experimental setups used for the synthesis experiments. In Chapter 3 a thermodynamic analysis of the La-Cr-Mg-O-H-Cl-Ar system is made in order to determine how the EVD process conditions may affect the incorporation of magnesium in LaCrO3, and to predict the range of experimental conditions for the synthesis of Mg-doped LaCrO3 by means of CVD (chemical vapor deposition)/EVD. In Chapter 4 the EVD stage of the growth process is modeled. The experimental results of the synthesis of Mg-doped LaCrO3 on porous and gastight substrates are described in Chapter 5. In Chapter 6 the first results on the synthesis of the perovskite oxide YCrO3, a material resembling LaCrO3, by means of particle-precipitation-aided CVD(PP-CVD) are described, as well as the principles of the process. ROUND-ROBIN VALIDATION EXERCISE FOR PLATE TWIST TEST METHOD
W. Nimmo and G. D. Sims Feb. 1995 25 p
(PB95-208088; NPL-DMM(A)156) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

A round-robin validation exercise has been undertaken to obtain precision data for the plate twist test method for determination of in-plane shear modulus. Six fiber-reinforced, polymer matrix composite materials representing a range of composite materials and shear moduli (1-6 GPa) were tested. The tests were undertaken by eight laboratories, seven of which had not previously used the method, according to the draft test procedure developed by National Physical Laboratory (NPL). The exercise was organized and the results were analyzed according to ISO 5275 using 95% confidence limits. The detailed results are given in Appendix 1. The test method has been studied and the improved analysis validated as part of the NPL program on test methods for composites. NTIS

INTERFACE DEGRADATION IN CAS/NICALON DURING ELEVATED TEMPERATURE AGING
K. P. Plucknett, R. L. Cain (Warwick Univ., Coventry, England.), and M. H. Lewis (Warwick Univ., Coventry, England.) 1995 7 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-008843; CONF-941144-115) Avail: CASI HC A02/MF A01

A CaO-Al2O3-SiO2 (CAS)/Nicalon glass-ceramic matrix composite has been subjected to elevated temperature oxidation heat-treatments between 375 and 1200 C, for up to 100 hours. Micro- and macro-mechanical properties have been determined by fiber push-down, using a mechanical properties microprobe, and flexure testing, respectively. Aging between 450 and 800 C results in significant property degradation, with reduced bending modulus and flexure strength, increased fiber sliding stress, and a transition to a purely brittle failure mode. Aging degradation is due to oxidative removal of the carbon interlayer, with the subsequent formation of a silica bond between fiber and matrix. At higher temperatures, carbon is retained due to the formation of a protective silica plug at exposed fiber ends, with the subsequent retention of composite properties. Short duration pre-treatment schedules, at 1000 or 1100 C, were developed to prevent intermediate temperature property degradation. DOE

IONIC CONDUCTIVITIES OF LITHIUM PHOSPHORUS OXYNITRIDE GLASSES, POLYCRYSTALS, AND THIN FILMS
B. Wang, J. B. Bates, B. C. Chakoumakos, B. C. Sales, B. S. Kwak, R. A. Zuhr, and J. D. Robertson (Kentucky Univ., Lexington, KY.) Nov. 1994 13 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-008898; CONF-941144-103) Avail: CASI HC A03/MF A01

Various lithium phosphorus oxynitrides have been prepared in the form of glasses, polycrystals, and thin films. The structures of these compounds were investigated by x-ray and neutron diffraction, x-ray photoelectron spectroscopy (XPS), and high-performance liquid chromatography (HPLC). The ac impedance measurements indicate a significant improvement of ionic conductivity as the result of incorporation of nitrogen into the structure. In the case of polycrystalline Li(2.88)PO(3.73)N(0.14) with the (gamma)-Li3PO4 structure, the conductivity increased by several orders of magnitude on small addition of nitrogen. The highest conductivities in the bulk glasses and thin films were found to be 3.0 x 10(exp -7) and 8.9 x 10(exp -7) S(center dot)/cm at 25 C, respectively. DOE

AN EXPLANATION FOR THE SHAPE OF NANOINDENTATION UNLOADING CURVES BASED ON FINITE ELEMENT SIMULATION
A. Bolshakov, G. M. Pharr (Rice Univ., Houston, TX.), and W. C. Oliver (Nano Instruments, Inc., Knoxville, TN.) 1995 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contracts DE-AC05-84OR-21400; DE-AC05-76OR-00033)
(DE95-008905; CONF-941144-99) Avail: CASI HC A02/MF A01

Current methods for measuring hardness and modulus from nanoindentation load-displacement data are based on Sneddon's equations for the indentation of an elastic half-space by an axially symmetric rigid punch. Recent experiments have shown that nanoindentation unloading data are distinctly curved in a manner which is not consistent with either the flat punch or the conical indenter geometries frequently used in modeling, but are more closely approximated by a parabola of revolution. Finite element simulations for conical indentation of an elastic-plastic material are presented which corroborate the experimental observations, and from which a simple explanation for the shape of the unloading curve is derived. The explanation is based on the concept of an effective indenter shape whose geometry is determined by the shape of the plastic hardness impression formed during indentation. DOE

OFF-POTENTIAL MEASUREMENT SYSTEMS FOR IMPRESSED CURRENT CATHODIC PROTECTION Final Report
Vincent F. Hock, Lewis F. Setliff, Wesley A. Houtz, Michael Noble, and Brad J. Lewis Sep. 1994 74 p

(DA Proj. 4A1-62784A-T41)
(AD-A290876; CERL-TR-FM-94/16) Avail: CASI HC A04/MF A01

The Army currently maintains more than 20,000 underground storage tanks, over 3000 miles of buried pipeline, and more than 3000 elevated water storage tanks, all requiring some form of corrosion control. Impressed current, cathodic protection (CP) systems are a widely used form of corrosion control for these structures. These CP systems contain numerous components that are susceptible to failure if not installed or maintained correctly. To ensure corrosion protection for a structure, the performance of a CP system must be determined in the field. This study investigated off-potential measurement systems-for impressed current CP systems in the laboratory and in the field. Commercially available off-potential measurement devices were investigated to test their reliability in recording off-potentials, which define the effectiveness of a CP system. Off-potential measurement devices were found to provide accurate system performance data. DTIC

MOLECULAR MODELING OF PMN CERAMICS Final Report

George J. Kavarnos Newport, IL 23 Jan. 1995 42 p
(NUWC Proj. A10016)
(AD-A290879; NUWC-NL-TR-10797) Avail: CASI HC A03/MF A01

Extended HOeckel theory was used to analyze the orbital interactions in PbNbO3(+) and LaNbO3(2+) model structures representative of lead magnesium niobate (PMN)ceramic. These structures were chosen to determine the orbital effects, if any, that an A-site substitutional such as Pb(2+) has on bond stability in the crystal lattice structure. It was determined that the A-site ion does not directly influence bonding between the A-site ion and atoms in the neighboring crystal lattice but does change the position of the Fermi level, which in PbNbO3(+) is -10.1 eV and in LaNbO3(2+) is -14.5eV. In PbNbO3(+), the Fermi level is so positioned that the bonds linking Nb and O are destabilized. In contrast, there is no antibonding character in LaNbO3(+). The shifting of the Fermi level as a function of the A-site ion is used to rationalize the experimental observation that pure PMN does not coarsen or undergo additional crystallization during annealing, but La-substituted PMN does in fact favor ordering of the crystal structure. MODELING OF THERMAL, ELECTRONIC, HYDRODYNAMIC, AND DYNAMIC DEPOSITION PROCESSES FOR PULSED-LASER DEPOSITION OF THIN FILMS

C. L. Liu, J. N. LeBoeuf, R. F. Wood, D. B. Geohegan, J. M. Donato, K. R. Chen, and A. A. Puretzky Nov. 1994 8 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-008906; CONF-941144-100) Avail: CASI HC A02/MF A01

Various physical processes during laser ablation of solids for pulsed-laser deposition (PLD) are studied using a variety of computational techniques. In the course of the authors combined theoretical and experimental effort, they have been trying to work on as many aspects of PLD processes as possible, but with special focus on the following areas: (1) the effects of collisional interactions between the particles in the plume and in the background on the evolving flow field and on thin film growth; (2) interactions between the energetic particles and the growing thin films and their effects on film quality; (3) rapid phase transformations through the liquid and vapor phases under possibly nonequilibrium thermodynamic conditions induced by laser-solid interactions; (4) breakdown of the vapor into a plasma in the early stages of ablation through both electronic and photoionization processes; and (5) hydrodynamic behavior of the vapor/plasma during and after ablation. The computational techniques used include finite difference (FD) methods, particle-in-cell model, and atomistic simulations using molecular dynamics (MD) techniques. DOE

INFLUENCE OF ADHESIVES AND BONDING TECHNIQUES ON THE PROPERTIES OF GLUED TIMBER-STEELPLATE JOINTS

1994 89 p
(PB95-211470; SP-RAPP-1994:39) Avail: CASI HC A05/MF A01

This research has been carried out as the first part of a project, whose aim is to develop a safe, simple, cost-effective frame joint for glulam constructions with large spans. Today traditional glulam frames are limited to a maximum span of about 60 m mainly due to transportation limitations. To facilitate the transportation of the structure, smaller glulam beams with glued-in steelplates could be prefabricated and sent to the building site. The joint could be mounted at the building site by means of welding or screwing. The influence of glues and glueing techniques on the joints' strength have been analyzed. NTIS

ENHANCEMENT OF PERFLUOROPOLYETHER BOUNDARY LUBRICATION PERFORMANCE: I. PRELIMINARY RESULTS

W. R. Jones, Jr., O. O. Ajayi (Wedeven Associates, Inc., Edgmont, PA.), A. J. Goodell (Wedeven Associates, Inc., Edgmont, PA.), L. D. Wedeven (Wedeven Associates, Inc., Edgmont, PA.), E. Devine (Swales and Associates, Beltsville, MD.), and R. E. Premore (National Aeronautics and Space Administration. Goddard Space Flight Center, Greenbelt, MD.) Jun. 1995 12 p Presented at the 207th National Meeting, San Deigo, CA, 13-18 Mar. 1994; sponsored the American Chemical Society
(RTOP 233-02-0D)
(NASA-TM-106937; E-9665; NAS 1.15:106937) Avail: CASI HC A03/MF A01

A ball bearing simulator operating under starved conditions was used to evaluate the boundary lubrication performance of a perfluoropolyether (PFPE) Krytox 143 AB. Several approaches to enhance boundary lubrication were studied. These included: (1) soluble boundary additives, (2) bearing surface modifications, (3) 'run-in' surface films, and (4) ceramic bearing components. In addition, results were compared with two non-perfluorinated liquid lubricant formulations. Based on these preliminary tests, the following tentative conclusions can be made: (1) substantial improvements in boundary lubrication performance were observed with a beta-diketone boundary additive and a tricresyl phosphate (TCP) liquid surface pretreatment; (2) the use of rough Si3N4 balls (Ra = 40 micro-in) also provided substantial improvement but with concomitant abrasive wear; (3) marginal improvements were seen with two boundary additives (a phosphine and a phosphatriazine) and a neat (100%) fluid (a carboxylic acid terminated PFPE); and surface pretreatments with a synthetic hydrocarbon, a PTFE coating, and TiC coated 440C and smooth Si3N4 balls (R(sub a) less than 1 micro-in); and (4) two non-PFPE lubricant formulations (a PAO and a synthetic hydrocarbon) yielded substantial improvements. ELECTRICAL CONDUCTIVITY STUDY ON POLYTHIOPHENES FILMS

I. Youm, M. Cadene (Montpellier-2 Univ., France), and D. Laplaze (Montpellier-2 Univ., France) Oct. 1994 8 p
(DE95-614309; IC-94/315) Avail: CASI HC A02/MF A01 (US Sales Only)

The electrical conduction mechanism of two classes of polythiophenes: polythiophene (PT) and poly(3-methylthiophene) (PMT) films containing various levels of doping counter-ions was investigated. The temperature dependence of electrical conductivity obeys the Mott equation based on variable range hopping. The dimension of the variable range hopping is correlated with the structure of the conducting polymer. It seems for these polymers that carrier transport via mobile conjugational defects does not play a detectable role. DOE

TEM-EXAMINATION OF CERAMIC-METAL INTERFACES

T. Torvund, O. M. Akselsen, O. Grong, and J. H. Ulvensoen 2 Jun. 1994 10 p
(PB95-196531; STF24-S94002) Avail: Issuing Activity (National Technical Information Service (NTIS))

In the present investigation, a novel approach to the examination of ceramic-metal interfaces by means of transmission electron microscopy (TEM) is described. A special composite material containing a SiC powder (50 micrometers) in a matrix of a Ag-4wt%Ti filler metal has been made for this purpose. The SiC-powder, mixed with the alloy, was held at 1,000 C for 20 minutes under high vacuum conditions. Thin foils were subsequently extruded from the sample. By combining EDS (energy dispersive spectrometry) and TEM examinations, both Ti5Si3 and TiC were disclosed

as reaction products. These are presumably the same constituent phases that form during brazing of SiC with Ag-4wt%Ti filler metals under similar conditions. NTIS

MECHANISMS OF ENHANCED IONIC CONDUCTION AT INTERFACES IN CERAMICS
D. Lubben and F. A. Modine Nov. 1994 13 p Presented at the 1994 Fall Meeting of the Materials Research Society, Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-009125; CONF-941144-108) Avail: CASI HC A03/MF A01

A large enhancement in the ionic conductivity of certain compounds occurs when the compound is produced as a composite material containing a finely-dispersed non-conductor such as SiO2 or Al2O3. This paper describes recent experiments which proposes that extended defects such as dislocations and grain boundaries, either resulting from or stabilized by the interface, are responsible for the enhancement. The ionic conductivities of LiI and CaF2 thin films grown on sapphire(0001) substrates were monitored in-situ during deposition as a function of film thickness and deposition conditions. LiI films grown at 27 C exhibited a region of enhanced conduction within 100 nm of the substrate and a lesser enhancement as the film thickness was increased further. This conduction enhancement was not stable but annealed out with a characteristic log(time) dependence. The observed annealing behavior was fit with a model based on dislocation motion which implies that the increase in conduction near the interface is due to extended defects generated during the growth process. CaF2 films grown at 200 C showed a behavior similar to the 27 C LiI films, with a region of thermally unstable enhanced conduction that occurs within 10 nm of the substrate. Amorphous Al2O3 films deposited over the CaF2 layers created no additional enhancement but did increase the stability of the conduction, consistent with an extended defect model. Simultaneous deposition of CaF2 and Al2O3 produced films consisting of very-fine -grained CaF2 and particles of amorphous Al2O3 (5-10 nm grain and particle size) a nd a high defect density which was stable even well above the growth temperature. Measured conduction in the composite at 200 C was approximately 360 times that of bulk CaF2. DOE

STRESS RELAXATION OF SILICON NITRIDE AT ELEVATED TEMPERATURES
A. A. Wereszczak, M. K. Ferber, T. P. Kirkland, E. Lara-Curzio, V. Parthasarathy (Solar Turbines, Inc. San Diego, CA.), and T. T. Gribb (Wisconsin Univ., Madison, WI.) 1995 10 p Presented at the 19th Annual Conference on Advanced Ceramics, Materials and Structures, Cocoa Beach, FL, 9-12 Jan. 1995
(Contract DE-AC05-84OR-21400)
(DE95-009177; CONF-950129-4) Avail: CASI HC A02/MF A01

The stress relaxation behavior of SN88, SN253, and NCX-5102 silicon nitride materials was experimentally determined in tension at 1300 C using buttonhead specimens. Specimens were held at constant strain after being loaded at 10 MPa/s to an initial stress of 276 MPa (40 ksi) or 414 MPa (60 ksi). The subsequent decay in tensile stress was measured as a function of time. A non-negative least squares algorithm used in conjunction with a generalized Maxwell model proved to be an efficient means to define characteristic relaxation modulus spectra and stress relaxation behavior. In the last part of this study, the utility of using short-term stress relaxation testing to predict long-term creep performance was examined. DOE

ANODICALLY ENHANCED DIFFUSION IN Cu/Ag THIN FILM COUPLES
Denny A. Jones and Alan F. Jankowski (Lawrence Livermore National Lab., Livermore, CA.) 1995 13 p Presented at the Alloy 600 Experts Meeting, Warrenton, VA, 5-9 Apr. 1993; sponsored by the Electric Power Research Inst.
(Contract DE-FC08-90NV-10891)
(DE95-009198; CONF-9304146-4) Avail: CASI HC A03/MF A01

Thin, 100-nm films of first silver and then copper were deposited consecutively onto pure single-crystal (111) silicon substrates by magneton sputter deposition. Controlled anodic current density was applied at room temperature to dissolve the outer copper film to varying depths approaching the copper/silver interface. Profiles of copper and silver concentration vs. depth below the anodically dissolved surfaces were subsequently obtained by argon ion sputtering and simultaneous Auger Electron Spectroscopy. Despite some intrinsic mixing during the profile analysis, there is clear evidence that diffusion of copper and silver into one another is enhanced by anodic currents at the outer copper surface. Preliminary interpretation leads the authors to believe that the effect is caused by surface formation of vacancies during anodic dissolution. The anodically generated vacancies can migrate as divacancies to the copper/silver interface where they enhance diffusion by the usual vacancy exchange mechanism. DOE

COMPATIBILITY OF REFRIGERANTS AND LUBRICANTS WITH MOTOR MATERIALS UNDER RETROFIT CONDITIONS Quarterly Technical Progress Report, 1 Oct. - 31 Dec. 1994
Robert Doerr and Todd Waite 12 Jan. 1995 83 p Prepared for Air-Conditioning and Refrigeration Technology Inst., Inc., Arlington, VA
(Contract DE-FG02-91CE-23810)
(DE95-010185; DOE/CE-23810/51B) Avail: CASI HC A05/MF A01

Motor materials were exposed to original refrigerants R-11, R-12, R-22, and R-502 in the presence of mineral oil for 500 hours. These same materials were then exposed to alternative refrigerants R-123, R-134a, R-407C (R-32/R-125/R-134a), and R-404A (R-125/R-143a/R-134a), respectively, in the presence of the appropriate lubricant for 500 hours. As a control, some samples were exposed to the original refrigerant/mineral oil for a total of 1,000 hours. These tests were conducted to determine whether exposure to the original refrigerant/mineral oil would affect compatibility of the motor materials with the alternative refrigerant/lubricant after retrofit. Motor materials exposed to the alternative refrigerant and lubricant (after an initial exposure to the original refrigerant and mineral oil) appeared to be compatible with the alternative refrigerant and lubricant. The only concerns were embrittlement of the polyethylene terephthalate (PET) sheet and sleeving insulations, and delamination and blistering of the Nomex sheet insulation in the R-22, R-502, and R-12. Embrittlement of the PET materials was attributed to moisture present during the exposure. Separation of the 475 varnish from metal surfaces in the R-123 was also a concern. The sheet and sleeving insulations were affected by the original refrigerant/mineral oil to a greater extent than by the alternative refrigerant and lubricant. DOE

POLARIZED RAMAN SPECTROSCOPY OF CHEMICALLY VAPOUR DEPOSITED DIAMOND FILMS
S. Prawer, K. W. Nugent, and P. S. Weiser 1994 11 p
(DE95-616776; UM-P-94/45) Avail: CASI HC A03/MF A01 (US Sales Only)

Polarized micro-Raman spectra of chemical vapor deposited diamond films are presented. It is shown that important parameters often extracted from the Raman spectra such as the ratio of the diamond to non-diamond component of the films and the estimation of the level of residual stress depend on the orientation of the diamond crystallites with respect to the polarization of the incident laser beam. The dependence originates from the fact that the Raman scattering from the non-diamond components in the films is almost completely depolarized while the scattering from the diamond components is strongly polarized. The results demonstrate the importance of taking polarization into account when attempting to use Raman spectroscopy in even a semi-quantitative fashion for the assessment of the purity, perfection and stress in CVD diamond films. POROUS SPHERICAL SHELLS AND MICROSPHERES BY ELECTRODISPERSION PRECIPITATION
Michael T. Harris, Warren G. Sisson, Osman A. Basaran, Susan M. Hayes, and Sophie J. Bobrowski 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society, Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-009073; CONF-941144-116) Avail: CASI HC A02/MF A01

The ability to reproduce the synthesis of dense- and porous-microspheres and micron-sized spherical shells is very important in (1) the development of ceramics for structural, electronic, catalyst and thermal applications; and (2) the encapsulation of products for controlled-release of drugs, flavors and perfumes, and inks and dyes, and the protection of light-sensitive components and mechanical support of fragile materials. Larger metallic- and ceramic-spherical shells have been used in inertial confinement fusion (ICF) experiments and as catalyst supports. The current paper will focus on a recent technique that has been developed for synthesizing ceramic microspheres and micro-shells. Pulsed electric fields have been used to enhance the dispersion of aqueous metal (Zr and Al) salt solutions from a nozzle and into a nonconducting liquid continuous phase that is immiscible with the aqueous phase. The diameter of the resulting microdroplets ranged in size from approximately 0.1 to 10 micrometers. Precipitation of hydrous metal oxides occurred as ammonia, which was dissolved in varying amounts in the continuous phase, diffused into the aqueous microdroplets. Spherical shells were formed at higher ammonia concentrations and microspheres were produced at lower ammonia concentrations. Upon drying, dimples appeared in the particles that were synthesized at higher ammonia concentrations. The latter result accords with the well known fact that under certain conditions spherical shells collapse when a fluid is extracted from the core of the particle. No dimples were observed in the microspheres that were produced at lower ammonia concentrations. Analog x-ray dot maps for aluminum and zirconium were done to determine the spatial distribution of each metal in the particles. DOE

CFC-REPLACEMENT BY NATURAL WORKING FLUIDS: R&D AND INDUSTRIAL CHALLENGES WITHIN THE REFRIGERATION, AIR CONDITIONING AMD HEAT PUMP AREAS
P. E. Frivik 6 Apr. 1994 34 p Presented at the Seminar on Heat Transfer, Thermophysical Properties and Cycle Performance of Alternative Refrigerants, Kitakyushu, Japan, 6-8 Dec. 1993 Prepared in cooperation with Norges Tekniske Hoegskole, Trondheim
(PB95-195756; STF11-A94037) Avail: Issuing Activity (National Technical Information Service (NTIS))

The chlorofluorocarbon (CFC) phase-out appears to be much slower in refrigeration, air conditioning and heat pump applications than in other areas. In addition to technical challenges and dependence on end-user decisions, the task is much bigger than most people outside of our industry are aware of. Although it is evident that the replacement will have to be done mainly with hydrochlorofluorocarbons (HCFC's) and hydrofluorocarbons (HFC's), there are questions about their long term use. The alternative can be natural working fluids, such as ammonia, CO2, and hydrocarbons, or water, air and noble gases. Such fluids are inherently safe for the global environment, due to their long term presence in the biosphere, but some of them pose challenges with respect to safety as well as to the need for improved or new processes, components and systems. COMPUTATIONAL MODELING OF COATING INTEGRITY EFFECTS ON IMPRESSED CURRENT CATHODIC PROTECTION SYSTEM Final Report, Aug. 1993 - Dec. 1994
Virginia G. DeGiorgi and C. P. Hamilton 28 Mar. 1995 16 p
(AD-A293256; NRL/MR/6380-95/7424) Avail: CASI HC A03/MF A01

Coatings are often used in conjunction with impressed current cathodic protection (ICCP) systems to minimize the effect of corrosion on marine structures. The presence of a coating reduces the current required by an ICCP system. The integrity and efficiency of the coating determines the level of current reduction achieved over the bare metal condition. One of the difficulties is designing a combined coating and ICCP system is that coatings deteriorate with time in service due to a variety of factors including mechanical wear and organic attack. Computational modeling is used to determine the variation in current demand required for corrosion protection for increased levels of damage to the protective coating applied to the propellers of a surface ship. For this material, an increase in RT crack growth resistance of greater than or equal to 300% was achieved; this property increases with increasing Nb particle size. SEM and in-situ crack growth observations show that crack bridging is the primary toughening mechanism for the increased crack growth resistance. A model was presented which uses existing models to determine the steady state bridging length given a stress intensity due to crack bridging. This model showed that the specimen size used for determining the RT fracture toughness was too small. It was also determined that the creep strain rate is in the same range as and comparable to existing studies of Al2O3 and Al2O3 systems. The creep mechanism of the composite material was found to be similar to that of unreinforced Al2O3 with a stress redistribution to the particle/matrix interface. DOE

NONLINEAR OPTICAL PROCESSES IN POLYMER FILMS Final Technical Report, 30 Sep. 1991 - 29 Sep. 1994
Anthony F. Garito 29 Sep. 1994 13 p
(Contract F49620-91-C-0100; DARPA Order 8103)
(AD-A293384) Avail: CASI HC A03/MF A01

Electrooptic organic polymer thin films show great promise for applications in integrated optoelectronic devices. These materials are usually formed as guest-host polymer systems that exhibit large second order nonlinear optical coefficients, low DC and microwave dielectric constants, and broad optical transparency ranges. The major obstacle to the development of practical polymer optoelectronic devices has been the thermal stability of the electrooptic coefficients of the guest-host polymer films. Current research has focused on finding new guest dye chromophores that possess large nonlinear optical coefficients and thermal stabilities greater than 300 degrees. We summarize our recent development of a new class of high thermal stability fused-ring chromophores, 1,8-naphthoylene

benzimidazoles, based on computer aided molecular design and experimental measurements of microscopic second order optical coefficients. The new chromophores were designed for their structural similarity to polyimide repeat units and consequent easy incorporation into high temperature host polyimides. They are highly colored, comparatively soluble in common organic solvents, and very stable in polyamic acid solutions. They possess relatively large second order optical coefficients and thermal stabilities exceeding 340 degrees. DTIC

FROM MOLECULAR TO MACROMOLECULAR LIQUID CRYSTALS
V. Percec 3 Apr. 1995 248 p
(Contract N00014-89-J-1828)
(AD-A293170) Avail: CASI HC A11/MF A03

The goal of this chapter is to discuss the dependence between various molecular parameters including structure, molecular weight, architecture, etc., and phase behavior. An attempt will be made to follow this trend on passing from a molecular to a macromolecular liquid crystal. The main goal is to provide the reader with the presently available tools which can be used to tailor-make liquid crystalline polymers. A brief and general introduction to low molar mass and polymeric liquid crystals which is required for this purpose will also be made. DTIC

Thirteen polymer coating systems on steel have been exposed to Pacific ocean water (NS) and artificial seawater (AS). Impedance data and electrochemical noise data have been obtained for two-electrode systems on a weekly basis. For comparison, three-electrode impedance measurements have been performed on a monthly basis. Noise data were obtained several times each week. The impedance and noise data at the Port Hueneme, CA test site (NS) were collected by an on-site computer system with a multiplexer which is controlled via modem by a computer system at CEEL/USC. In the laboratory a more traditional approach was used. Experimental data for two coating systems exposed to NS and AS for three months show that the experimental approach developed for data collection at a remote test site produced reliable results which were in general agreement with results obtained in the laboratory. GLASS MATRIX DOPED WITH ACTIVATED LUMINESCENT NANOCRYSTALLINE PARTICLES Patent Application
Alan L. Huston, inventor (to Navy) and Brian C. Justus, inventor (to Navy) 11 Jan. 1995 30 p
(AD-D017416; US-Patent-Appl-SN-371306) Avail: CASI HC A03/MF A01

A luminescent glass includes nanocrystalline semiconductor particles, such as ZnS nanocrystals, and an activator, such as copper, for the particles. The glass is made by depositing the nanocrystalline semiconductor particles and the activator within a porous glass matrix, such as 7930 Vycor and then thermally activating the glass. The porous glass matrix may be at least partially consolidated or may be allowed to remain porous. The nanometer particle size permits the luminescent glasses of the present invention to be transparent to its luminescent emissions. DTIC

This paper presents experimental data and computational modeling for a well-defined glass material. The experimental data cover a wide range of strains, strain rates, and pressures that are obtained from quasi-static compression and tension tests, split Hopkinson pressure bar compression tests, explosively driven flyer plate impact tests, and depth of penetration ballistic tests. The test data are used to obtain constitutive model constants for the improved Johnson-Holmquist (JH-2) brittle material model. The model and constants are then used to perform computations of the various tests. DOE

AN ASSESSMENT OF THE COST OF MICROWAVE SINTERING CERAMIC TILES FOR ARMOR APPLICATIONS. PHASE 2 REPORT
S. Das and T. R. Curlee Mar. 1995 56 p
(DE95-010000; ORNL/TM-12896) Avail: CASI HC A04/MF A01

This report documents work to assess the costs of microwave sintering ceramic tiles for armor applications. In the previous phase of work, the cost of microwave sintering and preliminary estimates of the total cost of microwave-sintered tiles under two microwave frequencies (i.e., 2.45 GHz and 28 GHz) for alumina and silicon carbide materials were reported. The second phase of work extends the previous work to include all pre- and post-sintering manufacturing steps and considers process and cost variations in these steps that may result from the adoption of microwave sintering. Two separate models were developed for two different materials. As before, a process-cost approach was utilized within a spreadsheet environment. When compared to conventional sintering, the manufacturing of microwave-sintered alumina armor tiles will require an additional binder removal step prior to microwave sintering. The base-case cost of microwave-sintered alumina tiles is estimated to be $46.80/part and $50.50/part, given the use of 2.45 GHz and 28 GHz microwave power sources, respectively. In the case of microwave sintering of silicon carbide armor tiles, the material preparation step will be significantly different from conventional sintering. Instead of a binder removal step, there will be a green machining step. The base-case cost of microwave-sintered silicon carbide tiles is estimated to be $324.50/part and $327.50/part for 2.45 GHz and 28 GHz microwave power sources, respectively, compared to $235/part for conventionally-sintered tiles. Several sensitivity analyses of the impacts of variations in key economic and technical parameters on the costs of microwave-sintered tiles were conducted. Those analyses indicate that costs are quite sensitive to changes in the quantity of energy required during sintering. DOE

MAGNETIC RESONANCE SPECTROSCOPY OF FULLERENES AND (PI)-CONJUGATED POLYMERS Ph.D. Thesis
P. A. Lane 20 Oct. 1994 120 p
(Contract W-7405-eng-82)
(DE95-010131; IS-T-1717) Avail: CASI HC A06/MF A02

Photophysics of two pi-conjugated systems, buckminsterfullerene and pi-conjugated polymers, were studied using photoluminescence-detected magnetic resonance (PLDMR). PLDMR of C60 and C70 dissolved in toluene/polystyrene glasses and of fullerene films is described. PLDMR of the glasses is due to a triplet exciton delocalized over the entire molecule; that of (sup 3)C70 differs from (sup 3)C60 due to its longer triplet lifetime. In the films, the delocalized triplet, distorted by intermolecular interactions, reveals a half-field resonance due to triplet-triplet fusion; a second triplet localized on a pentagon or hexagon face next to a neighbor molecule is also detected. Narrow PL-enhancing resonances at g = 2.0017 and 2.0029 for C60 and C70 are observed; these are attributed to recombination of long-lived charged polarons. PLDMR of photooxidized and photopolymerized C60 and C70 reveals a third triplet exciton delocalized across several molecules. The PLDMR of a number of pi-conjugated polymer systems showed three features: (1) a narrow PL-enhancing polaron resonance, and (2) broad full- and (3) half-field triplet exciton powder patterns. PLDMR on fullerene-doped polymers indicate that polarons and triplet excitons quench the PL and are stabilized by defects which break the conjugation. Results on conjugated polymers incorporating noncarbon atoms suggest that these sites trap both polarons and triplet excitons, increasing their lifetimes and populations. This and other results on electroluminescent devices implies that the energy levels of the polarons are distributed over a significant range. DOE

SERVICES TO DEVELOP, STANDARDIZE, AND VALIDATE POLYMERASE CHAIN REACTION (PCR) PROTOCOLS FOR THE DETECTION OF LEISHMANIASIS IN CLINICAL SAMPLES Final Report, Sep. 1992 - Sep. 1994
Frank A. White, III and Kalachar Suryanaarayana 17 Oct. 1994 126 p
(Contract DAMD17-92-C-2097)
(AD-A290155) Avail: CASI HC A07/MF A02

The disease Leishmaniasis, endemic in Africa, South West Asia, and South America, is caused by transmission of a parasite of the Leishmania species via the bite of an infected sandfly. The severity of the disease ranges from cutaneous lesions to a frequently fatal visceralization of the internal organs unless treated at an early stage. Detection of the parasite is difficult because only low numbers of infected cells are found in peripheral blood. Existing tests for Leishmania parasites are time consuming and have high (50%) false negative rates. We report the development of a rapid polymerase chain reaction (PCR) based diagnostic capable of detecting 1-10 infected cells in 1.5 x 10(exp 6) PBMC's or 2-5 mls of peripheral blood. The test has an accuracy greater than 92%, and a false negative rate of less than 8%, when validated against known clinical samples. Author

A COMPARISON OF COATING ALTERNATIVES FOR US COAST GUARD AIRCRAFT Final Report, for Apr. 1993 - Aug. 1994
Donald J. Hirst and Stephen J. Spadafora 12 Dec. 1994 21 p
(AD-A293270; NAWCADWAR-95014-43) Avail: CASI HC A03/MF A01

Current coatings used on U.S. Coast Guard aircraft contain high volatile organic compound (VOC) contents. Federal, state and local environmental agencies restrict the amount of VOC's from the use of these materials through legislation such as the Clean Air Act and local Air Quality Management District Rules. At the request of the Coast Guard, the Naval Air Warfare Center Aircraft Division Warminster investigated several low VOC candidate replacements to the current paint scheme. The physical performance properties of these materials (i.e. corrosion resistance, adhesion, etc.) were characterized using standard coatings tests. The results of this program show that there are several acceptable alternatives. Replacement of current coating systems would reduce the total amount of hazardous materials emitted from Coast Guard painting operations and eliminate the need for expensive control equipment which will be required by the Clean Air Act (resulting in substantial future cost savings). POLARIZED LASER INDUCED HOLOGRAPHIC SURFACE RELIEF GRATINGS ON POLYMER FILMS Technical Report, 1 Oct. 1994 - 30 Sep. 1995
D. Y. Kim, Lian Li, V. Shivshankar, J. Kumar, and S. K. Tripathy 4 Apr. 1995 27 p
(Contract N00014-90-J-1148)
(AD-A293275; Rept-1148-95-04) Avail: CASI HC A03/MF A01

Large amplitude holographic surface relief gratings on azobenzene containing polymer films were optically induced without any subsequent processing steps. The surface relief structures were observed upon exposure to an interference pattern of polarized Ar+ laser beams. The surface relief structures were investigated using atomic force microscopy. Very regularly spaced surface grating with a surface modulation depth of over 1000 A was obtained. The gratings were stable at ambient conditions and the samples were reusable after erasing the gratings by heating the film above the glass transition temperature. The orientation of the azobenzene groups were induced first and followed by the surface deformation process. The polarization of the writing beam had significant effect on the surface modulation process. The relation between the surface change and optically induced orientation of the azobenzene groups was discussed. Thermal effects were also investigated by studying the dependence of writing intensity and grating spacing on the grating formation process. DTIC

USE OF A VARIABLE FREQUENCY SOURCE WITH A SINGLE-MODE CAVITY TO PROCESS CERAMIC FILAMENTS
Gerald J. Vogt, Amy H. Regan, Anton S. Rohlev, and Michael T. Curtin 1995 9 p Presented at the 97th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 30 Apr. - 1 May 1995
(Contract W-7405-eng-36)
(DE95-010992; LA-UR-95-1440; CONF-950401-2) Avail: CASI HC A02/MF A01

Rapid feedback control is needed for practical microwave processing of continuous ceramic oxide filaments to regulate the process temperature where the dielectric properties of the filaments change rapidly with temperature. A broadband traveling wave tube (TWT) amplifier provides a highly versatile process control platform for filament processing. By comparing a RF signal from the cavity to a reference signal from the TWT, phase information can be used in a negative feedback loop to allow the oscillator to track the cavity frequency as it shifts due to the changing

dielectric constant in the filaments being heated. By sampling the field level in the cavity with a detector, amplitude control can be done to maintain a consistent electric field level in the cavity, which is important for controlling the filament heating and temperature. The system design will be discussed along with application data for commercial ceramic samples. DOE

LOW TEMPERATURE FABRICATION FROM NANO-SIZE CERAMIC POWDERS Final Report
Edward J. Gonzalez, Gasper J. Piermarini, Bernard Hockey, Subhas G. Malghan, Stephen C. Danforth (Rutgers Univ., Piscataway, NJ.), and Alexander Pechenik (Department of the Air Force, Washington, DC.) 28 Apr. 1995 83 p Prepared in cooperation with National Inst. of Standards and Technology, Gaithersburg, MD
(Contract DE-AC05-84OR-21400)
(DE95-010995; ORNL/SUB-92-22041/02) Avail: CASI HC A05/MF A01

Understanding of compaction and rheology of ceramic powders is needed for production of defect-free greenware. High pressure and lubricating media (liq. N2, pentane) were used for increased green body density. High green densities could be achieved with nanosize Si nitride and (gamma) alumina. A pressure/temperature system was built which uses an Instron screw-driven press and a piston/cylinder die. Max random packing density of 57 +/- 2% theoretical was achieved for dry compaction of Si nitride at 2.5 GPa and RT; compaction under liq. N2 gave 64 +/- 2%. Dry compaction of alumina was 64% theoretical at 2.5 GPa. Pressureless sintering of Si nitride green compacts did not result in further densification. Hot pressing increased the hardness. In alumina, increased compaction pressure enhances the (gamma)-(alpha) transition and increases the densification upon heat treatment. It is difficult to obtain dense material without coarsened pore/grain microstructure. SANS showed alumina results similar to those found for materials made by inert-gas-condensation. Theoretical studies were also made to model the compaction process. Future studies are outlined. DOE

CRACKING DURING NANOINDENTATION AND ITS USE IN THE MEASUREMENT OF FRACTURE TOUGHNESS
D. S. Harding, G. M. Pharr (Rice Univ., Houston, TX.), and W. C. Oliver (Nano Instruments, Inc., Knoxville, TN.) 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-008839; CONF-941144-106) Avail: CASI HC A02/MF A01

Results of an investigation aimed at developing a technique by which the fracture toughness of a thin film or small volume can be determined in nanoindentation experiments are reported. The method is based on the radial cracking which occurs when brittle materials are deformed by a sharp indenter such as a Vickers or Berkovich diamond. In microindentation experiments, the lengths of radial cracks have been found to correlate reasonably well with fracture toughness, and a simple semi-empirical method has been developed to compute the toughness from the crack lengths. However, a problem is encountered in extending this method into the nanoindentation regime with the standard Berkovich indenter in that there are well defined loads, called cracking thresholds, below which indentation cracking does not occur in most brittle materials. We have recently found that the problems imposed by the cracking threshold can be largely overcome by using an indenter with the geometry of the corner of a cube. For the cube-corner indenter, cracking thresholds in most brittle materials are as small as 1 micron (approximately 0.1 grams). In addition, the simple, well-developed relation between toughness and crack length used for the Vickers indenter in the microindentation regime can be used for the cube-corner indenter in the nanoindentation regime provided a different empirical constant is used. DOE

SYNTHESIS AND SELECTED MICRO-MECHANICAL PROPERTIES OF TITANIUM NITRIDE THIN FILMS BY THE PYROLYSIS OF TETRAKIS TITANIUM IN AMMONIA
Y. W. Bae, W. Y. Lee, T. M. Besmann, P. J. Blau, and L. Riester 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-010224; CONF-941144-127) Avail: CASI HC A02/MF A01

Thin films of titanium nitride were chemical vapor deposited on (100)-oriented single-crystal silicon substrates from tetrakis (dimethylamino) titanium, Ti((CH3)2N)4, and ammonia gas mixtures in a cold-wall reactor at 623 K and 655 Pa. The films were characterized by Auger electron spectroscopy, X-ray diffraction, and transmission electron spectroscopy. The nano-scale hardness of the film, measured by nanoindentation, was 12.7 +/- 0.6 GPa. The average kinetic friction coefficient against unlubricated, type 440 C stainless steel was determined using a computer-controlled friction microprobe to be approximately 0.43. DOE

BEHAVIOUR OF POLYMERS IN RADIOACTIVE ENVIRONMENTS: EFFECTS OF DOSE SPEED [COMPORTAMIENTO DE POLIMEROS EN AMBIENTES RADIACTIVOS: EFECTOS DE LA VELOCIDAD DE DOSIS]
A. S. Docters and M. E. Gonzalez 1993 3 p In SPANISH Presented at the 21st Meeting of the Argentine Association of Nuclear Technology, Mar del Plata, Argentina, 8-12 Nov. 1993
(DE95-621008; INIS-AR-091; CONF-9311167) Avail: CASI HC A01/MF A01 (US Sales Only)

The scope of this research is to determine the degradation of mechanical properties of cable insulating PVC after irradiation in air at a Cobalt-60 ((gamma)-ray) facility. Amongst the mechanical properties elongation at break and tensile strength were chosen as they are the most sensible to radiation. The samples were exposed to combined radiation-thermal environments with constant airflow in order to obtain accelerated aging data at doses up to 50-300 kGy, with dose rates ranging between 1.3 and 5.6 kGy/h at temperatures from 60 C to 100 C. At lower dose rates the degradation of mechanical properties increased after the same total dose: elongation at break decreases sharply while tensile strength decreases to a less extent, showing dose rate effects. A strong synergy between irradiation and thermal processes was also observed. DOE

N95-31272 Department of the Navy, Washington, DC.
PHTHALONITRILE PREPOLYMER AS HIGH TEMPERATURE SIZING MATERIAL FOR COMPOSITE FIBERS Patent
Teddy M. Keller, inventor (to Navy) 14 Feb. 1995 6 p Filed 28 Jun. 1993
(AD-D017447; US-Patent-5,389,441; US-Patent-Appl-SN-082645; US-Patent-Class-428-395) Avail: US Patent and Trademark Office

Sized fibers, for use as reinforcements in high temperature polymeric composites, are prepared by coating the outside surface of the fibers with an amorphous, B-stage bisphthalonitrile prepolymer. The prepolymer may be prepared by curing a bisphthalonitrile monomer with an organic amine, an aromatic organic acid, a mineral acid, a Lewis acid or a salt of any of the above. Then, the fibers are coated by passage through an organic solution of the prepolymer. Either before or after completely curing the prepolymer coating on the fibers, the coated fibers are covered with a resin, for example, by passage through a solution or melt of a polyimide or bisphthalonitrile resin. If the phthalonitrile coating was incompletely cured prior to covering the phthalonitrile-coated fiber with the resin, the heat during the subsequent cure of the resin also completely cures the phthalonitrile coating. The resulting composite has excellent high temperature properties. In a preferred embodiment, the coated fibers are used to form a prepreg for usage in composite fabrication. DTIC

SUBSTRATE HEATING MEASUREMENTS IN PULSED ION BEAM FILM DEPOSITION
J. C. Olson, H. A. Davis, D. J. Rej, W. J. Waganaar, D. R. Tallant (Sandia National Labs., Albuquerque, NM.), and M. O. Thompson (Cornell Univ., Ithaca, NY.) 1995 7 p Presented at the Spring Meeting of the Materials Research Society, San Francisco, CA, 17-21 Apr. 1995
(Contract W-7405-eng-36)
(DE95-010862; LA-UR-95-1281; CONF-950412-4) Avail: CASI HC A02/MF A01

Diamond-like Carbon (DLC) films have been deposited at Los Alamos National Laboratory by pulsed ion beam ablation of graphite targets. The targets were illuminated by an intense beam of hydrogen, carbon, and

oxygen ions at a fluence of 15-45 J/sq cm. Ion energies were on the order of 350 keV, with beam current rising to 35 kA over a 400 ns ion current pulse. Raman spectra of the deposited films indicate an increasing ratio of sp(sup 3) to sp(sup 2) bonding as the substrate is moved further away from the target and further off the target normal. Using a thin film platinum resistor at varying positions, we have measured the heating of the substrate surface due to the kinetic energy and heat of condensation of the ablated material. This information is used to determine if substrate heating is responsible for the lack of DLC in positions close to the target and near the target normal. Latest data and analysis will be presented.

INTELLIGENT SYNTHETIC POLYMERS Final Report, Jun. 1991 - Dec. 1994
Paul D. Calvert and H. K. Hall, Jr. 1 Mar. 1995 10 p
(Contract DAAL03-91-G-0169)
(AD-A292905; ARO-28900.13-MS) Avail: CASI HC A02/MF A01

Block copolymers of hydrophobic and hydrophilic acrylates were to be made and tested for control of mineralization by calcium oxalate. Acrylate copolymers in solution inhibited crystal growth to an extent dependent on their acid content but not dependent on the architecture. Solid films of acrylate polymers became mineralized when exposed to oxalate solutions. This effect was very dependent on the structure of the polymer. Methods were also developed for forming inorganic layers on polymer films by overlaying two polymers, each containing solubilized precipitants. Reaction and precipitation would occur at the film/film interface. Cross-linked methacrylic acid films could be templated with rigid molecules such as caffeine, and then would be absorb the templated molecule selectively from solution. Methods were also developed for coupling short protein chains to acrylate polymers as a route to combining biochemical specificity with localization on inorganic surfaces.

(Contract N00014-89-J-3063)
(AD-A292880) Avail: CASI HC A03/MF A01

In this project we seek to use this variability of solvating power to dissolve high molecular weight polymers, provide solution processing capacity for polymers which are typically difficult to process, and produce blends of normally incompatible polymers from cosolvated mixtures. This last area, polymer blends, this one of great potential and interest because traditional polymer blends are often phase separate into large domains. For example, we expect that by molecularly blending a liquid crystallize polymer with long chain, fiber forming, crystalline polymers, we will reduce the macroscopic phase separation that now limits effective utilization of both the LCP (liquid crystal polymers) reinforcement and the matrix polymer processibility.

DEPOSITION AND CHARACTERIZATION OF PHOTOCONDUCTIVE PZT THIN FILMS
C. T. Lin, L. Li, J. S. Webb, M. S. Leung (Aerospace Corp., El Segundo, CA.), and R. A. Lipeles (Aerospace Corp., El Segundo, CA.) El Segundo, CA Aerospace Corp. 1 Sep. 1994 17 p
(Grant NSF CTS-93-12875)
(ATR-93(8308)-7) Avail: CASI HC A03/MF A01

Deposition by Aqueous Acetate Solution (DAAS) technique was used to synthesize highly crystalline thin films of undoped and 2 percent iron-doped Pb(Zr(0.53)Ti(0.47))O3 (PZT) perovskites on sapphire and Pt-coated silicon substrates at 600 C. Iron ions were added either at the precursor stage or by thermal diffusion. The crystallinity of the film was measured by X-ray diffraction. The ferroelectric activity was examined by polarization-voltage (P-E) hysteresis loops. The electro-optical properties of ferroelectric/photoconductive PZT thin films were investigated by photocurrent action and 77K emission spectroscopies. The photoconductivity measured at visible wavelengths was enhanced for the thermally diffused, but not the precursor-processed doped materials. This, together with lattice parameters obtained from X-ray data and P-E hysteresis loop measurements, suggested that the precursor-processed doped ions are strongly bonded in the perovskite lattice, whereas the thermally diffused ions are more weakly bound in the grain boundaries.

CONJUGATED AROMATIC POLYIMINES. 2. SYNTHESIS, STRUCTURE, AND PROPERTIES OF NEW AROMATIC POLYAZOMETHINES
Chen-Jen Yang and Samson A. Jenekhe 20 Mar. 1995 68 p
(Contract N00014-94-1-0540)
(AD-A292955; TR-5) Avail: CASI HC A04/MF A01

A series of 20 conjugated aromatic Polyimines, containing p-phenylene, p-biphenylene, p-terphenylene, 4,4'- stilbene, and 1,5-naphthalene linkages in the backbone and various electron-donating and electron-withdrawing side-group substitutions, have been synthesized, characterized, and used to investigate the effects of molecular structure on the electronic structure and properties of conjugated polymers. Soluble gallium trichloride or diarylphosphate complexes of the aromatic polyimines in organic solvents facilitated their solution spectroscopic characterization and their processing into thin film and coatings. Electrochemical reduction of the aromatic polyimines was reversible with formal potential of -1.93 to -1.52 V (SCE) and 0.22 to 0.86 charge transferred whereas oxidation was irreversible. The electron affinity and ionization potentials of the series of polymers varied from 2.46 to 2.94 eV and from 4.80 to 5.38 eV, respectively. The associated LUMO and HOMO energy levels are thus tunable by up to 0.48 eV and 0.58 eV, respectively. The electrochemically and optically determined LUMO-HOMO energy gaps of thin films were very close and in the range of 2.08-2.77 eV. The results of this study show that aromatic polyimines are an interesting class of pi-conjugated polymers whose structure and properties can be regulated over a wide range by variation in backbone structure, side group substitution, and through intramolecular hydrogen bonding or complexation, backbone planarity.

EXCITED-STATE COMPLEXES OF CONJUGATED POLYMERS: NOVEL PHOTOPHYSICAL PROCESSES AND OPTOELECTRONIC MATERIALS
Samson A. Jenekhe 20 Mar. 1995 5 p
(Contract N00014-94-1-0540)
(AD-A292958; TR-7) Avail: CASI HC A01/MF A01

Although the ground-state charge transfer complexes of pi-conjugated polymers have been widely investigated in the past two decades, the corresponding excited-state complexes were only recently discovered. The results of our extensive studies of intermolecular excimers and exciplexes of many conjugated polymers will be presented in the talk. The observation of excimer and excimer emission of many conjugated polymers provides a new model of the photophysics of the materials. It will be shown that the modified Birks' mechanism of intermolecular excimers can explain all the essential features of the luminescence of conjugated polymers. The luminescence and charge photogeneration in exciplexes of conjugated polymers with donor triarylamines will also be presented.

EFFECTS OF MOLECULAR STRUCTURE ON THE ELECTROACTIVE AND OPTICAL PROPERTIES OF CONJUGATED RIGID-ROD POLYBENZOBISAZOLES
John A. Osaheni and Samson A. Jenekhe 20 Mar. 1995 55 p
(Contract N00014-94-1-0540)
(AD-A292968; TR-6) Avail: CASI HC A04/MF A01

The effects of molecular structure on the electronic structure and electrochemical and linear optical properties of a series of pi-conjugated

rigid-rod polybenzobisazoles, including three new polymers, were explored by cyclic voltammetry and measurement of the optical dispersion of the refractive index. The electrochemical reduction of the polymers was reversible whereas oxidation was not reversible in accord with the electron deficient nature of the benzobisazole ring. The observed variation of the reduction and oxidation potentials, electron affinity, and ionization potential of the series of polymers was related to the variation in backbone structure. The electron affinity of the polymers was 2.4 to 3.0 eV which indicated that the LUMO energy level was tunable by up to 0.6 eV. The ionization potential (5.2 to 5.7 eV) and associated HOMO level of the polymers was tunable by up to 0.5 eV. The measured wavelength dispersion of the refractive index of the polybenzobisazoles showed that n(lambda = 1064 nm) and n(lambda = 2500 run) were 1.74-2.03 and 1.55-1.95 respectively. The large refractive index variation with molecular structure was satisfactorily accounted for by the competing effects of polarizability and molar volume. These results provide a basis for understanding the electronic, optoelectronic, and optical properties of the conjugated polybenzobisazoles in terms of the underlying molecular and electronic structures. (Contract F33615-92-C-3405)

(AD-A292992; WL-TR-94-3064) Avail: CASI HC A03/MF A01

Today polymers are increasingly used in advanced structural applications such as aircraft canopies. However, there are no well established models which could be used by design engineers for predicting time to failure for these materials. Development of adequate criteria for three basic stages of fracture (crack initiation, stable crack growth and dynamic crack propagation) is necessary for the accurate prediction of service lifetime. Part 1 of this report reflects a recent progress in understanding of various failure initiation mechanisms in transparency-grade Polycarbonate (PC). A new fatigue crack initiation map for PC is proposed. Another important stage of the fracture process which may strongly influence the total lifetime is crack propagation. Propagation of a crack surrounded by the process zone is a well-known phenomenon for the PC. The properties of the material in the process zone may strongly influence such critical fracture parameters as lifetime, fracture toughness, etc. The deformation of PC by shear banding at a notch-tip was found very similar to that obtained by cold-drawing of PC. In Part 2 of this report the tensile cold-drawing (necking) behavior of PC is further examined using simple tensile extension coupled with temperature measurements via an infrared camera. DTIC

COMPOSITE POLYMER ELECTROLYTE FOR LITHIUM BATTERIES Technical Report, Jul. 1994 - Feb. 1995

Steve Slane and Mark Salomon Mar. 1995 17 p

(AD-A293924; ARL-TR-426) Avail: CASI HC A03/MF A01

Composite polymer electrolyte films consisting of zeolite powders dispersed in poly(acrylonitrile)(PAN) based gels with lithium hexafluoroarsenate have been prepared and their electrochemical properties studied. Gel electrolytes prepared by adding lithium hexafluoroarsenate in propylene carbonate (PC) and ethylene carbonate (EC) mixtures with PAN have demonstrated ionic conductivities greater than 0.001 siemens per cm at room temperature and above. The addition of zeolite powders increased ionic conductivity at low temperatures due to the highly amorphous nature of the composite film. Impedance spectroscopy was performed to study the lithium electrode/electrolyte interface, and a reduction of the passivation kinetics was observed. Cyclic voltammetry showed that addition of PAN and zeolite powder to liquid electrolyte mixtures with EC/PC did not change the stable electrochemical potential window. In Li/lithium cobalt dioxide cells, at 25 C, these composite electrolytes demonstrated current densities as high as 0.5 milliamps per sq cm, with little voltage or capacity loss compared to cells with liquid electrolytes. The goal of this research has been to find dispersants for ceramic processing applications. The polyelectrolytes currently in use in the industry are synthesized from toxic precursors which present health hazards to workers. We have investigated polyelectrolytes produced from natural sources such as bacteria and kelp, as well as some polymers which have been produced synthetically. The polyelectrolytes which we have investigated include polysaccharides (alginate and dextran) and polypeptides (polyglutamic acid and polyaspartic acid). Some have been obtained from cultures of bacteria grown in our laboratories, others have been obtained from chemical supply houses. In addition, we have investigated the feasibility of using an in situ process by which we incubate the polymer-producing bacteria in the presence of ceramic powders. In this system, polymer adsorbs to the powder in a high affinity state, allowing subsequent washing to remove the bacterial cells, while retaining the adsorbed polymer. DTIC

MODE I LARGE STRAIN VISCOELASTIC CRACK BEHAVIOR IN NITRILE RUBBER SHEETS Final Report

Claudia J. Quigley and Joey L. Mead Oct. 1994 41 p

(AD-A289984; ARL-TR-513) Avail: CASI HC A03/MF A01

A finite element analysis of a Mode I crack in a viscoelastic, hyperelastic, and incompressible material was performed under relaxation conditions. Loading of the finite element model was applied until the far field strain reached 50%; the viscoelastic material was then allowed to relax for 15 minutes. The numerical results were compared to experimental material behavior. The applied load and stretch ratio histories obtained from the finite element analysis agreed closely with experimental results. The S22 stress component was the dominant stress and possessed a singularity of o(r(sub -1)), similar to the asymptotic solution for a mechanical crack tip stress field, which does not include viscoelasticity, in a hyperelatic material. The order of the singularity did not change with relaxation. Examination of the crack tip stress field showed that maximum stresses were found close to the crack surface suggesting that crack propagation should initiate above and below the deformed crack tip. CHARACTERIZATION OF /11'01/ TWIN DISLOCATION STRUCTURES IN EVAPORATED TITANIUM THIN FILMS BY HREM

Y. Kasukabe (Tohoku Univ., Sendai, Japan.), Y. Yamada (Tohoku Univ., Sendai, Japan.), Pengju Lin, and L. A. Bursill 1994 16 p

(DE95-615391; UM-P-92/86) Avail: CASI HC A03/MF A01 (US Sales Only)

The structure of /11'01/ twin dislocations in Ti films evaporated on NaCl substrates at 250 C has been examined and characterized by high-resolution electron microscopy. The results have revealed that a twin dislocation structure with step height 4 x d(K(sub 1)), where d(K(sub 1)) is the spacing of the /11'01/ twin planes, actually dissociates into two /11'01/ twin dislocations with step heights of d(K(sub 1)) and 3 x d(K(sub 1)). The twin dislocation with a step height of 3 x d(K(sub 1)) contains an edge dislocation in the core while that with a step height of d(K(sub 1)) is a simple classical twin dislocation structure. Twin dislocations with step height of 2 x d(K(sub 1)), including an edge dislocation in the core, also occur. The atomic-scale core structures of /11'01/ twin dislocations may be derived by analysis of the high-resolution images. The relative mobilities of the three types of twin dislocations is then discussed. DOE

SOLUTION BASED TEMPERATURE OF PEROVSKITE-TYPE OXIDE FILMS AND POWDERS Ph.D. Thesis

J. M. McHale, Jr. Apr. 1995 210 p

(Contract W-7405-eng-36)

(DE95-009089; LA-12825-T) Avail: CASI HC A10/MF A03

Conventional solid state reactions are diffusion limited processes that require high temperatures and long reaction times to reach completion. In this work, several solution based methods were utilized to circumvent this diffusion limited reaction and achieve product formation at lower temperatures. The solution methods studied all have the common goal of trapping the homogeneity inherent in a solution and transferring this

homogeneity to the solid state, thereby creating a solid atomic mixture of reactants. These atomic mixtures can yield solid state products through 'diffusionless' mechanisms. The effectiveness of atomic mixtures in solid state synthesis was tested on three classes of materials, varying in complexity. A procedure was invented for obtaining the highly water soluble salt, titanyl nitrate, TiO(NO3)2, in crystalline form, which allowed the production of titanate materials by freeze drying. The freeze drying procedures yielded phase pure, nanocrystalline BaTiO3 and the complete SYNROC-B phase assemblage after ten minute heat treatments at 600 C and 1100 C, respectively. Two novel methods were developed for the solution based synthesis of Ba2YCu3O(7-x) and Bi2Sr2Ca2Cu3O10. Thin and thick films of Ba2YCu3O(7-x) and Bi2Sr2Ca2Cu3O10 were synthesizedby an atmospheric pressure, chemical vapor deposition technique. Liquid ammonia solutions of metal nitrates were atomized with a stream of N2O and ignited with a hydrogen/oxygen torch. The resulting flame was used to coat a substrate with superconducting material. Bulk powders of Ba2YCu3O(7-x) and Bi2Sr2Ca2Cu3O10 were synthesized through a novel acetate glass method. The materials prepared were characterized by XRD, TEM, SEM, TGA, DTA, magnetic susceptibility and electrical resistivity measurements. DOE

COMPATIBILITY OF SINGLE HYDRAULIC FLUID WITH MILITARY SPECIFICATION FLUIDS, SEALS AND METALLURGY

Ellen M. Purdy and Donna M. Rutkowski Mar. 1995 18 p

(AD-A292954; TRDEC-TR-13620) Avail: CASI HC A03/MF A01

This report documents the results of compatibility studies designed to determine the compatibility of Single Hydraulic Fluid (SHF) with currently used military specification hydraulic fluids (MIL-H- 6083, MIL-H-46170), elastomer seals, and hydraulic system metallurgy. The evaluations consisted of subjecting various elastomer samples including nitrile, polyacrylate, and fluorocarbon to SHF by itself and SHF mixed at various percentages with MIL-H-6083 and MIL-H-46170, determining their volume and hardness change, then immediately subjecting them to immersion in SHF. The elastomers were again examined for any net change in hardness and volume after the sequential immersion. Finally, SHF compatibility was tested with the elastomers and the metallurgy in each other's presence to determine if any decomposition in elastomers or fluid or metallurgy occurs. It was found that SHF is fully compatible with MIL-H-6083 and MIL-H-46170 and the existing metallurgy. SHF was also found to be completely compatible with 5 of the 6 elastomers tested. The only exception was fluorosilicone which exhibited anomalous behavior in the sequential fluid testing. It performs well in SHF by itself and when immersed in fluid mixtures of SHF and MIL-H-6083 or MIL-H-46170, yet it exhibited significant shrinkage when subjected to SHF after immersion in the other fluids. This behavior cannot be explained in the scope of this evaluation. Further examination will be required to determine if fluorosilicone seals can be used successfully with SHF. DTIC

RECYCLING MIL-H-46170 HYDRAULIC FLUID TO EXTEND FLUID SERVICE LIFE Final Report, 1 Oct. 1993 - 31 Aug. 1994

Ellen M. Purdy, Donna M. Rutkowski, and Franklyn D. Sterling Mar. 1995 19 p

(AD-A293035; TARDEC-TR-13619) Avail: CASI HC A03/MF A01

This report documents the laboratory efforts in proving that used hydraulic fluid could be recycled by removing contaminants and mixing with new fluid. Once the used fluid has been filtered to remove solid particulate contamination and dehumidified to bring the moisture content below 500 ppm water, it can be mixed with new fluid in a 75:25 ratio to bring the fluid mixture up to specification performance. The recycled used fluid by itself could not pass the foaming characteristic requirement thus requiring re-inhibition. Instead of adding more antifoaming agent to the fluid, the decision was made to mix recycled fluid with new fluid to provide the re-inhibition effect. Mixing in new fluid results in an enhancement of all additive performance and eliminated any possible problems with adding too much or too little anti-foaming agent. These efforts set the standards for evaluating commercial recycling units that can recycle hydraulic fluid on a large scale and also establish doctrine for successfully extending the service life of used hydraulic fluid. DTIC

EVALUATION OF ENVIRONMENTALLY ACCEPTABLE HYDRAULIC FLUIDS Final Report, Oct. 1993 - Sep. 1994

In-Sek Rhee, Carlos Velez, and Karen VonBernewitz Mar. 1995 23 p

(AD-A293037; TARDEC-TR-13640) Avail: CASI HC A03/MF A01

This describes the laboratory evaluation of environmentally acceptable (EA) commercial hydraulic fluids formulated with vegetable oils and synthetic esters. Evaluations included viscosity, flammability, corrosion and wear protection, thermal and oxidation stability, low temperature capability, elastomer compatibility, and storage stability. Results showed the vegetable based products were limited in operational temperature ranges (-10 to 90 C) due to poor thermal and low temperature stabilities. On the other hand, synthetic ester based fluids showed a wide operational capability (-40 to 150 C) which can meet the requirements of military mobile hydraulic fluids. Although EA hydraulic fluids did not meet the current military specification requirements they are potentially good candidate fluids for the replacement of some current petroleum based military hydraulic fluids. DTIC

AN INTERPENETRATING POLYMER NETWORK FOR SECOND-ORDER NONLINEAR OPTICS Technical Report, 1 Oct 1994 - 30 Sep. 1995

L. Li, J. I. Chen, S. Marturunkakul, J. Kumar, and S. K. Tripathy 23 Mar. 1995 18 p

(Contract N00014-90-J-1148)

(AD-A293019; TR-95-01) Avail: CASI HC A03/MF A01

The linear optical and second order nonlinear optical (NLO) properties of an interpenetrating polymer network (IPN) have been investigated. For the poled and cured IPN samples, large second order NLO coefficients, d(sub 33), were measured at 1.064 and 1.542 micron. The linear electrooptic coefficients, r(sub 33), were determined at various wavelengths. The poled and cured IPN samples showed no measurable decay of the second-order optical nonlinearity after being treated at 110 C for more than 1000 hours. This excellent long-term stability of the NLO property is ascribed to the novel interpenetrating crosslinked molecular structure of the IPN system. DTIC

DIELECTRIC PROPERTY MEASUREMENT OF ZIRCONIA FIBERS AT HIGH TEMPERATURES

Gerald J. Vogt, Wayne R. Tinga (Alberta Univ., Edmonton, Alberta.), and Ross H. Plovnick (Minnesota Mining and Mfg. Co., Saint Paul, MN.) 1995 14 p Presented at the 97th Annual Meeting of the American Ceramic Society, Cincinnati, OH, 30 Apr. - 1 May 1995

(Contract W-7405-eng-36)

(DE95-010991; LA-UR-95-1459; CONF-950401-1) Avail: CASI HC A03/MF A01

Using a self-heating, electronically tunable microwave dielectrometer, the complex dielectric constant of zirconia-based filaments was measured at 915 MHz from 350 to 1100 C. This fibrous material cools rapidly to near room temperature within several seconds due to a large surface area to volume ratio. Such rapid sample cooling necessitates the use of a self-heating technique to measure the complex dielectric constant at temperatures up to 1100 C. Sample temperature was measured with optical fiber thermometry. The effect of sample temperature measurement on data accuracy is discussed. DOE

N95-32025# Oak Ridge National Lab., TN.

PREDICTIONS OF TENSILE BEHAVIOR AND STRENGTHS OF A SI3N4 CERAMIC AT HIGH TEMPERATURES BASED ON A VISCOPLASTIC MODEL

K. C. Liu, R. Brinkman, Jow-Lian Ding, and Shenghin Lin 1995 7 p Presented at the ASME International Gas Turbine and Aeroengine Congress and Exposition: Land, Sea and Air, Houston, TX, 5-8 Jun. 1995

(Contract DE-AC05-84OR-21400)

(DE95-010220; CONF-950629-5) Avail: CASI HC A02/MF A01

Tensile deformation and rupture behavior were simulated using a viscoplastic model developed recently. The model was formulated based on the state variable approach, which provides flexibility and versatility for characterizing the time-dependent behavior of ceramic materials under general thermomechanical loading conditions. Simulations portrayed by the model were compared with experimental tensile data obtained under two

different tensile stressing rates. Results showed that the model was capable of simulating deformation behavior for all practical engineering purposes, but estimated high-temperature fracture strengths somewhat conservatively. DOE

MICROSTRUCTURE OF Al2O3 IRRADIATED WITH AN APPLIED ELECTRIC FIELD
S. J. Zinkle, J. D. Hunn, and R. E. Stoller 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-010278; CONF-941144-133) Avail: CASI HC A02/MF A01

A thin amorphous film of alumina was irradiated with 2-MeV He(sup +) ions at (approximately) 400 C up to a damage level of about 0.01 displacements per atom (dpa). The alumina films were sufficiently thin ((approximately) 1.8 (mu)m) to allow the ion beam to be completely transmitted through the specimen. An electric field of (approximately) 280 V/mm (dc) was applied continuously during the irradiation. Radiation induced electrical degradation (RIED), i.e. a permanent increase in the conductance of the film, was observed in specimens irradiated at temperatures near 400 to 450 C but did not occur in a specimen irradiated above 500 C. Transmission electron microscopy found no evidence for colloid formation. The observed increase in the conductance of the alumina film may be due to radiation-induced microcracking. DOE

Gelcasting of silicon metal for the production of sintered reaction bonded silicon nitride (SRBSN), was investigated in order to identify associated advantages over conventional forming techniques; i.e., die and isostatic pressing. Compacts were formed from identical powder mixtures by both gelcasting and pressing, and were nitrided and sintered to produce SRBSN ceramics. Characterization of the samples included measurement of green density, green and nitrided pore structure, weight gain during nitridation, final density, microstructure, toughness, and flexural strength. It was found that a more uniform pore structure existed in the green gelcast samples. It is believed that this pore configuration aided in nitridation, and manifested itself in a more uniform final microstructure. In addition, improved mechanical properties were achieved in the gelcast samples. This improvement can be attributed to green microstructure homogeneity. DOE

MODELS OF TRANSPORT, GAS-PHASE AND SURFACE CHEMISTRY IN DIAMOND CHEMICAL VAPOR DEPOSITION
D. S. Dandy and M. E. Coltrin 1995 7 p Presented at the 187th Meeting of the Electrochemical Society, Reno, NV, 21-26 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-009861; SAND-95-0583C; CONF-950518-4) Avail: CASI HC A02/MF A01

This paper presents an analysis of the Chemical Vapor Deposition of diamond thin films in a direct-current (dc) arc-jet reactor. The analysis discussed here includes a model of the performance of the arc-jet hydrogen excitation source, chemistry in the free-stream region, diffusive transport and chemistry in the boundary layer and at the surface. The surface chemistry model includes pathways for deposition of diamond, as well as creation of defects in the diamond lattice. DOE

THE PYROCHLORE-TO-PEROVSKITE TRANSFORMATION IN SOLUTION-DERIVED LEAD ZIRCONATE TITANATE THIN FILMS
James A. Voigt, B. A. Tuttle, T. J. Headley, and D. L. Lamppa 1995 7 p Presented at the 4th Material Research Society-Ferroelectric Thin Films Conference, Boston, MA, 5-9 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-010453; SAND-95-0735C; CONF-941267-1) Avail: CASI HC A02/MF A01

The authors have characterized the pyrochlore-to-perovskite crystallization process in solution-derived Pb(Zr(0.20)Ti(0.80))O3 thin films on (100)MgO single crystal substrates. It has been determined that the perovskite phase nucleated preferentially at the film/MgC interface out of a nanocrystalline (approx. 100 angstrom grains) pyrochlore matrix. During the early stages of the pyrochlore-to-perovskite conversion process, perovskite growth proceeded nearly isotropically from the substrate to form hemispherically shaped grains. Deviations from isotropic growth were shown to result from a growth dependence based on the crystallographic orientation of a growing perovskite grain relative to the orientations of pyrochlore grains being transformed. The volume change that occurs during the pyrochlore-to-perovskite transformation along with two-dimensional grain growth has been used to develop a mechanism for formation of porosity that commonly is concentrated in grain boundary regions. LOW COST FABRICATION OF SILICON CARBIDE BASED CERAMICS AND FIBER REINFORCED COMPOSITES
M. Singh and S. R. Levine Jul. 1995 15 p
(Contract NAS3-27186; RTOP 537-04-10)
(NASA-TM-107001; E-9216-1; NAS 1.15:107001) Avail: CASI HC A03/MF A01

A low cost processing technique called reaction forming for the fabrication of near-net and complex shaped components of silicon carbide based ceramics and composites is presented. This process consists of the production of a microporous carb/ ı preform and subsequent infiltration with liquid silicon or silicon-refractory metal alloys. The microporous preforms are made by the pyrolysis of a polymerized resin mixture with very good control of pore volume and pore size thereby yielding materials with tailorable microstructure and composition. Mechanical properties (elastic modulus, flexural strength, and fracture toughness) of reaction-formed silicon carbide ceramics are presented. This processing approach is suitable for various kinds of reinforcements such as whiskers, particulates, fibers (tows, weaves, and filaments), and 3-D architectures. This approach has also been used to fabricate continuous silicon carbide fiber reinforced ceramic composites (CFCC's) with silicon carbide based matrices. Strong and tough composites with tailorable matrix microstructure and composition have been obtained. Microstructure and thermomechanical properties of a silicon carbide (SCS-6) fiber reinforced reaction-formed silicon carbide matrix composites are discussed. Author

INFLUENCE OF STORAGE ON THE MAXIMAL PULL-OUT FORCE OF THREE DIFFERENT OPTICAL FIBERS FROM THREE EPOXIDES [INVERKAN AV LAGRING PA MAXIMALA UTDRAGSKRAFTEN AV TRE OLIKA OPTISKA FIBRER FRAN TRE EPOXIDER]
T. Karlsson Dec. 1994 17 p In SWAHILI
(PB95-211777; FOA-R-94-00075-2.5-SE) Avail: Issuing Activity (National Technical Information Service (NTIS))

Three different optical fibers were embedded in three different epoxies. After 1.5 to 12 months storage, either in room atmosphere or at 40 C and 80% relative humidity, the maximum force for fiber pull-out was measured. Storage in moisture increased the maximum pull-out force by the swelling of the matrices. The thermal shrinking during cooling of the matrices crosslinked at elevated temperatures also increased the pull-out force. After storage for a month, in ambient air or moisture, the shrinkage had

relaxed. However the bond between the quartz fiber and its plastic cover did not seem to be changed by the storage. NTIS

(Contract DE-FG05-88ER-13859)
(DE95-011578; DOE/ER-13859/T1) Avail: CASI HC A03/MF A01

This report summarizes the progress made on the subject project from its beginning up to near the end of the last project year and describes their plans for the end of the year. During the grant period, the authors have (1) developed a theoretical model permitting the calculation of the adsorption energy distribution from the isotherm without making any assumptions regarding the experimental isotherm, by contrast with what current methods do; (2) coded, tested, and validated the calculation procedures developed, which involved solving serious computational difficulties; (3) carried out a systematic investigation of the propagation of the experimental and model errors made in the chromatographic measurements to the energy distribution derived from these data; (4) prepared series of columns with silica particles of various origins, virgin or bonded with different groups; and (5) determined the adsorption energy distributions of diethylether, methanol, ethanol, n-heptane, pyridine, and tetrahydrofuran on the surfaces of several of these adsorbents. (DE95-010542; DOE/CE-15599/T2) Avail: CASI HC A02/MF A01

The goal of this project is to investigate the physical properties of an in-situ whisker reinforced glass ceramic material and to produce prototype heat exchanger tubes for testing in a coal combustion environment. The in-situ whisker reinforced glass ceramic process was developed and patented at Virginia Tech and licensed to MATVA. Successful completion of this project will demonstrate the potential for this new material to replace existing heat exchanger materials due to its superior chemical and physical properties. This report covers the progress made during this period. Topics covered here are glass melting and sample preparation. Density and microstructure results are given for samples. DOE

In a joint Cooperative Research and Development Agreement (CRADA) between Martin Marietta Energy Systems (MMES) and an industrial partner, Y-12 has been evaluating nondestructive evaluation (NDE) techniques to identify the quality of high strength aluminum oxide tubes used in laser applications. In Phase 1, several NDE techniques were developed to inspect the tubes. In Phase 2 a correlation between detected defects, actual failure mode and strength of the tubes was developed. In Phase 2 the industrial partner supplied tubes manufactured under a variety of conditions and containing material defects expected from process control variations. The tubes were inspected at MMES utilizing a variety of available acoustic techniques. After inspection, ring tensile specimens were fabricated to determine the tensile strength. The data were evaluated utilizing Weibull statistics to determine the statistical impact of the defects upon strength and correlate the data with the nondestructive evaluations of the tubes and observed defect distribution. The purpose of this study is to extend the concept of micellar polymerization to more complex systems, and to explore the responsive nature of hydrophobically modified polyelectrolytes by tailoring the microstructure. The synthesis of hydrophobically modified acrylamide/acrylic acid copolymer is described. These types of polymers are of interest as thickening agents utilized in enhanced oil recovery. DOE

Measurements of aging properties of composite propellants with polysulfide as fuel-binder have been made. Tensile strength, adhesion of liner, thermal expansion, glass transition temperature, hardness and burning rate have been measured. The results have been compared with measurements on propellants from the same sort of motors in USA and with earlier measurements at Forsvarets Forskningsanstalt (FOA). The results now obtained correspond well with earlier results. No indications of deterioration of properties since the last test at FOA can be seen. NTIS

The work represents a contribution toward the quantitative understanding of certain energy trapping and release processes of the molecular level for novel compounds. In particular, it has dealt via advanced computations with questions of formation, properties as equilibrium and at transition states, and of spontaneous or laser-induced fragmentation of unusual molecules existing because of local minima on repulsive surfaces. Such molecules are a number of new nonclassical hydrogen complexes (e.g. OBeH2, F3AlH2, F4Mg2 H2). For diatomic volcanic and excimer states, newly developed ab initio computational methods were applied for obtaining the time-dependent probabilities for a number of multiphoton dissociation and excitation processes. SURVEY OF RECENT Al2O3 DROPLET SIZE DATA IN SOLID ROCKET CHAMBERS, NOZZLES, AND PLUMES c20
Mark Salita *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 1-18 (For primary document see N95-31194 11-28)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The size distribution of Al2O3 droplets in a solid propellant rocket is very different in the chamber, nozzle, and plume, primarily due to breakup and collision/coalescence in the nozzle. This paper attempts to summarize, evaluate, and relate the results of 19 recent experimental and analytical studies of droplet size in order to construct a unified model of droplet size evolution from the chamber through the nozzle and into the plume. It is believed that the distribution of droplet mass in the chamber is bimodal log-normal, with 1 micron smoke comprising about 80% of the mass and 50-100 micron caps comprising the remaining 20%. During passage through the nozzle, the caps shatter to product droplets whose diameters are about 10% of the caps but still 10 times those of smoke, while all but 1-2% of the smoke mass collides and coalesces with the shatter products to generate an essentially monomodal mass distribution at the nozzle exit whose D43 agrees with Hermsen's correlation and whose standard deviation alpha approximately or equal to 0.13 is smaller than both the chamber smoke (alpha approximately or equal to 0.40) or caps (alpha approximately or equal to 0.20). Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A discussion is presented of the current state of understanding and prediction of size and spatial distribution of aluminum and Al2O3 droplets in a motor. It is noted that available theory and experimental results are inadequate for prediction of two phase flow effects (e.g., slag formation, damping of oscillations), especially with propellants other than those based on AP and hydrocarbon binder. Potentially important phenomena that have received almost no attention include fragmentation of Al droplets near burnout, and growth of larger oxide droplets by accretion of fine 'smoke' droplets. SHUTTLE REDESIGNED SOLID ROCKET MOTOR ALUMINUM OXIDE INVESTIGATIONS **c20**
Fred S. Blomshield, Karl J. Kraeutle, and Richard A. Stalnaker *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 29-40 (For primary document see N95-31194 11-28)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

During the launch of STS-54, a 15 psi pressure blip was observed in the ballistic pressure trace of one of the two Space Shuttle Redesigned Solid Rocket Motors (RSRM). One possible scenario for the observed pressure increase deals with aluminum oxide slag formation in the RSRM. The purpose of this investigation was to examine changes which may have occurred in the aluminum oxide formation in shuttle solid propellant due to changes in the ammonium perchlorate. Aluminum oxide formation from three propellants, all having the same formulation, but containing ammonium perchlorate from different manufacturers, will be compared. Three methods have been used to look for possible differences among the propellants. The first method was to examine window bomb movies of the propellants burning at 100, 300 and 600 psia. The motor operating pressure during the pressure blip was around 600 psia. The second method used small samples of propellant which were fired in a combustion bomb which quenched the burning aluminum particles soon after they left the propellant surface. The bomb was fired in both argon and Nitrogen atmospheres at various pressures. Products from this device were examined by optical microscopy. The third method used larger propellant samples fired into a particle collection device which allowed the aluminum to react and combust more completely. This device was pressurized with Nitrogen to motor operating pressures. The collected products were subdivided into size fractions by screening and sedimentation and analyzed optically with an optical microscope. the results from all three methods indicate very small changes in the size distribution of combustion products. BURN TIME MEASUREMENTS OF SINGLE ALUMINUM PARTICLES IN STEAM AND CARBON DIOXIDE MIXTURES **c25**
S. E. Olsen and M. W. Beckstead *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 41-58 (For primary document see N95-31194 11-28)
(Grant AF-AFOSR-0152-91)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

In this study, single aluminum particles (40 to 80 micron) were burned in H2O/CO2 mixtures. Burn times were measured electronically using a PMT (photomultiplier). In addition, the effect of oxidizer composition was determined. Burn times were also measured for single particles, quenched at various stages of combustion. SEM (scanning electron microscopy) micrographs of quenched specimens were obtained. The results were used in determining particle burn times. Study of quenched particles revealed the formation of large hollow aluminum oxide spheres nearly the size of the original aluminum particles. These spheres have been reported by other investigators at both atmospheric and high pressure conditions. It was found that burn time measurements are very sensitive to the method of analysis used. Using the results of an aluminum combustion model by Brooks, effective oxygen concentrations were calculated for this work and other data. A relationship exists between the effective oxygen concentration and burn times reported for a given diameter. The particle burn times measured in this work compare well with other data if the effective oxygen concentration is properly accounted for. Author

AN INVESTIGATION OF THE SIDE-DUMP DUAL IN-LINE RAMJET COMBUSTOR **c07**
M. W. Deppe, R. F. Salyer, and D. W. Netzer *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 59-74 (For primary document see N95-31194 11-28)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Three inlet-side-dump ramjet-combustor geometric configurations were investigated using non-intrusive water-tunnel flow visualization techniques to qualitatively determine optimum flame-stablization dome lengths and fuel-injection locations and to investigate whether new configurations may be more capable of providing high combustion efficiencies under wide operating limits. The optimum dome lengths which provided good fuel distribution and steady mixing all had lengths between 0.31 and 1.4 combustor diameters. Fuel injection in a narrow region on the upstream side of the dump inlet was the only location found capable of distributing fuel into the flame-holding region. Multiple injection locations in the inlet were required to distribute fuel uniformly into the main combustion region. Based upon the flow visualization results a dual, axially-inline, side-dump, liquid-fueled ramjet combustor was designed and tested. Particle size distributions from the fuel atomizers were measured both in ambient conditions and under hot-air, contra-flow engine conditions. Data obtained under ambient conditions were found to have little value for the engine flow environment. This geometry provided improved flammability limits and combustion efficiency at lean fuel-air ratios. Direct fuel injection into the recirculation was required for sustained combustion at lean equivalence ratios for the single side-dump configuration, but not for the dual in-line configuration. The fuel distribution in the inlet duct that is required for good flammability limits and combustion efficiency was opposite to that required to prevent pressure oscillations. A dump angle of 45 deg resulted in lower than desired combustion efficiencies, apparently due to poor mixing from the aft inlet. Author

ENHANCED ENERGY RELEASE AND SOOT REDUCTION IN ACTIVELY CONTROLLED FLAMES **c25**
E. J. Gutmark, T. P. Parr, D. M. Hanson-Parr, and K. C. Schadow *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 75-84 (For primary document see N95-31194 11-28)
(Contract N00014-93-WX-24268)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

An active control system designed to reduce soot formation and increase energy release was demonstrated in open and enclosed flames. The control is based on synchronized periodic injection of fuel (ethylene) into air vortices at a timing which ensures energizing of the vortices and homogeneous mixing. It was shown that dual fuel injection during a single air vortex period can reduce the soot formation by several orders of magnitude relative to an unforced flame and doubles the flame temperature. Laser diagnostics were utilized to obtain planar simultaneous visualizations of the mixing process between the fuel and air flows as well as the combustion zone, indicated by OH, and soot production regions. It was shown that a proper timing of fuel injection results in homogeneous fuel/air mixing within the vortices, while injection which is out of phase with the proper one results in interference with the vortex formation and islands of unmixed fuel, leading to poor combustion and a sooty flame. The interaction of the flame with the external air was studied using particle Imaging Velocimetry (PIV). It was determined that the entrained air is crucial to maintain control authority on the flame. Blockage of the entrained external air resulted in the loss of control. A method for substitution for the external air by direct injection of air into the flame base was developed. Its efficacy was demonstrated in open and enclosed systems. The latter is especially significant due to the lack of air rich flow in the ambient of such systems. The secondary air injection doubled the flame temperature near the flame holder of an enclosed flame. Author

A PULSED LIQUID FUEL RAMJET **c07**
K. J. Wilson, E. J. Gutmark, R. A. Smith, and K. C. Schadow *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 85-99 (For primary document see N95-31194 11-28)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A new design concept for a liquid-fueled-ramjet with increased efficiency is presented. The concept utilizes vortex combustion, a method which is based on the idea that by confining the combustion process to occur within vortices it is possible to use several advantageous features of vortical flow: combined bulk mixing of the reactants with intense fine-scale mixing leading to enhanced molecular mixing, long residence time to achieve complete combustion, localized high temperature regions, and an easily

controllable environment. The concept was initially tested in laboratory scale ethylene diffusion flames. Air vortices were stabilized by acoustically forcing a turbulent air jet at its most unstable mode. Fuel was injected into the air vortices synchronously with the vortex formation sequence. The proper timing of the process was determined to be critical; when the vortex formation, the ambient air entrainment induced by the vortices and fuel injection occurred in a certain sequence the fuel burning was more complete and the energy release increased significantly. The pulsed ramjet design is based on these basic principles. The liquid fueled ramjet is a coaxial dump combustor with an axial air inlet. A pulser located in the air inlet conduit produces pressure pulses in the inlet flow using spark ignition of premixed fuel/air which generates a train of flame kernels. These growing kernels interact with the jet flow to stabilize air vortices within the combustor. Liquid fuel injectors at the dump plane inject fuel into the vortices at a controlled frequency and timing. The pulser also supplies a periodic ignition source which stabilizes the flame and extends the lean flammability limit. This design ensures that the energy release occurs close to the dump plane and that the fuel is consumed in the region of highest local temperature to obtain maximum heat release within minimal combustion chamber length. EXPERIMENTS IN A 120-mm RAM ACCELERATOR INCLUDING FLOW VISUALIZATION **c25**

David L. Kruczynski *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 101-114 (For primary document see N95-31194 11-28)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A technique to visualize transient and steady combustion phenomena in ram accelerators using sacrificial transparent acrylic chambers is demonstrated. This technique allows the normal operating environment of ram accelerators to be very closely approximated. Using this technique, details of the environment during the transient starting phase as the projectile enters the accelerator and the obturator is discarded are seen for the first time. In addition, steady or running combustion around the projectile after the obturator has been shed is captured. These flow visualizations are shown to be useful in validating computational fluid dynamics codes and in providing guidance in reducing projectile unstarts while increasing initial accelerator performance. NUMERICAL SIMULATION OF RAM ACCELERATOR PERFORMANCE INCLUDING TRANSIENT EFFECTS DURING INITIATION OF COMBUSTION AND SENSITIVITY STUDIES **c25**

Michael J. Nusca *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 115-128 (For primary document see N95-31194 11-28)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Computational fluid dynamics solutions of the full Navier-Stokes equations have been used to numerically simulate the reacting in-bore flowfield for the ram accelerator projectile propulsion system. In this system a projectile and obturator are injected at supersonic velocity into a stationary tube filled with a pressurized mixture of hydrocarbon, oxidizer and inert gases. Flow stagnation on the obturator initiates combustion of the mixture. A system of shock waves generated on the projectile, in conjunction with viscous heating, sustains combustion. The resulting energy release, which travels with the projectile, also generates high pressures that impart thrust to the projectile. Numerical simulations utilizing finite-rate chemical kinetics have been used to investigate this flowfield. Numerical results are used to visualize the flowfield, predict effects of variation in system parameters, and predict projectile in-bore velocity. Author

Systematic experimental investigations of the regimes of heat release and Mach number in which the ram accelerator will operate have been carried out at the University of Washington in methane/oxygen/nitrogen and hydrogen/oxygen/methane propellant mixtures. Several distinct mechanisms have been identified which limit the peak velocity that can be reached in a particular propellant mixture for the projectile configurations used in the investigations. Maximum and minimum propellant energetics were determined by decreasing and increasing the diluent concentration until the immediate cessation of thrust was observed as the projectile entered the test mixture. Within these energetic limits there is a relatively wide range of diluent concentrations that will accelerate the projectile beyond the Chapman-Jouguet (CJ) detonation speed of the propellant mixture. These effects are readily seen by plotting the experimental results in the heat release-Mach number plane. The projectile acceleration was almost always terminated by an unstart. the most energetic mixtures unstarted immediately with no observed projectile acceleration. The Mach number obtained in the test section increased to a maximum as the propellant energetics were reduced. After reaching the optimal mixture, the unstart Mach number steadily decreased as the energetics were further reduced until combustion could no longer be supported. The phenomena which determine how the unstart Mach number depends on propellant energetics are the topics of this study. Propellant mixtures with less heat release than the optimum for peak Mach number consistently unstart at velocities approximately 30% above the CJ speed. Variations in projectile geometry and materials are used to experimentally investigate the unstart mechanisms in this chemistry regime. Preliminary results indicate that the nose cone material has a significant effect on the unstart Mach number. Comparison of experiments in the two different types of propellant mixture confirm that Mach number and heat release are the primary variables that determine ram accelerator performance. The analytical and experimental results of these investigations are discussed in this paper. Author

PULSE FORMING NETWORK IN THE ETC COMBUSTION CHARACTERIZATION OF PLASMA AUGMENTED SOLID PROPELLANTS **c25**

M. DelGuercio, H. Burden, I. Stobie, K. White, G. Katulka, and S. Driesen *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 177-188 (For primary document see N95-31194 11-28)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The combustion of solid propellants, subjected to plasma augmentation, has been studied with a 300 kJ maximum stored energy pulse forming network (PFN) in the range of 1 kJ/g of electrical energy over a 1.2-ms pulse length. The need to characterize the effects of such plasma augmentation on propellant combustion over a longer pulse length is the motivation for the upgrading of the aforementioned PFN to a maximum stored energy output of 400 kJ with a 2.4-ms pulse length. In this report the theoretical calculations, PFN upgrade design and fabrication details, will be provided. Also discussed are the modifications to a plasma generator resulting from test firings. VISCOUS HEATING OF LIQUID LAYERS UNDER INTENSE SHEAR

H. Yuan and A. Prosperetti *In its* The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 325-334 (For primary document see N95-31194 11-28)

(Contract DAAL04-93-G-0409)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Viscous heating under high shear has been proposed as a possible cause for the accidental ignition of liquid monopropellants. A typical experiment consists in the rapid compression of a drop of liquid between two parallel nearly-rigid planes. This process is simulated numerically by solving the full Navier-Stokes equations. It is found that allowing for the

decrease of viscosity with increasing temperature leads to a peak temperature reduction of nearly an order of magnitude. On the basis of these results it would seem that accidental ignition by viscous heating is an unlikely event. Author

NUMERICAL STUDY OF SHEAR-INDUCED HEATING IN HIGH-SPEED NOZZLE FLOW OF LIQUID MONOPROPELLANT
J. Katz, X. Shi, and O. M. Knio *In its* The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 335-344 (For primary document see N95-31194 11-28)
(Contract DAAH04-93-G-0413)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A numerical study is performed which focuses on peak temperatures experienced by a liquid monopropellant during high-speed injection in a small-diameter nozzle. Attention is focused on short-duration injection during which the nozzle wall boundary layer is predominantly laminar. An unsteady 1D analysis of the temperature distribution associated with sudden fluid acceleration over a flat insulated boundary is first conducted. Expressions are provided which relate the normalized peak wall temperature to the prevailing Eckert, and Prandtl numbers. Results reveal a quadratic dependence of the normalized wall temperature on impulse velocity, and a nonlinear variation with Prandtl number. Next, simulation of high-speed flow in an axisymmetric nozzle is performed. The numerical schemes are based on finite-difference discretization of a vorticity-based formulation of the mass, momentum and energy conservation equations. Implementation of the numerical schemes to flow of LP 1846 in a 4mm-diameter nozzle indicates that preignition is likely to occur for velocities higher than 200 m/s. The effects of wall heat transfer and temperature-dependent properties are also discussed. Author

WORKSHOP REPORT: MEASUREMENT TECHNIQUES IN HIGHLY TRANSIENT, SPECTRALLY RICH COMBUSTION ENVIRONMENTS c25
Todd E. Rosenberger *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 345-354 (For primary document see N95-31194 11-28)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

With the emergence of advanced propulsion systems such as liquid propellant (LP), electrothermal-chemical (ETC), electromagnetic (EM), conventional hypervelocity, and in-bore ramjet, the measurement of combustion phenomena has become more complex. the data associated with these systems can be rich in high-frequency components, and share similar transient behavior. Measurement techniques associated with conventional solid propellant systems are not always capable of accurately recording these phenomena. The accuracy of pressure and acceleration measurements in combustion chambers, barrels, and on-board projectiles has been compromised by the lack of a fundamental understanding of the effects of the mounting configuration and the mechanical and electrical components of the transducer on the integrity of the measurement. Consequently, the system development and technical understanding of the physical processes involved in the ignition and combustion of such advanced propulsion systems have been compromised. A workshop was needed to bring together experts from the aforementioned and related communities to disseminate knowledge of lessons learned and to discuss the techniques necessary to make high-fidelity pressure measurements in these environments. This paper states the objectives, identifies the participants who met to address them, provides a list of the technical presentations made, presents highlights from these presentations and the discussions that they prompted, and ends with conclusions and recommendations which came out of the workshop. PRESSURE TRANSDUCER PERFORMANCE AND MEASUREMENT TRADE-OFFS IN A TRANSIENT, HIGH TEMPERATURE, COMBUSTION ENVIRONMENT c25
Todd E. Rosenberger, Joseph W. Colburn, Carl R. Ruth, John R. Hewitt, Melvin B. Ridgley, James F. Tuerk, and Arthur A. Koszoru *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 355-374 (For primary document see N95-31194 11-28)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

At the U.S. Army Research Laboratory (ARL), a series of tests were performed in a 120-mm cannon to characterize the effects of transducer type, transducer port configuration, thermal protection media, and severe mechanical forces on the amplitude and frequency response of the pressure measurement. A ring of five pressure transducer ports (82 deg apart) was machined 2.6 m from the rear face of a 120-mm gun tube. The physical configuration of the transducer ports consisted of three single-diameter ports with varying stand-off distances, a conventional two-diameter port, and a blind port. As the projectile passed the longitudinal position the pressure transducers were exposed to a transient, high temperature environment which allowed the investigators to study the fidelity of the pressure measurement under transient, high temperature, mechanically adverse gun conditions. These tests demonstrated that the use of single-diameter pressure ports with cavity depths of 0.254 mm (0.010 in) and 0.711 mm (0.030 in) will more accurately characterize the oscillatory nature of the pressure measurement than would the use of a single-diameter port with a cavity depth of 1.600 mm (0.060 in). It was determined that thermal protection filling materials have a notable effect on the measurement. In addition, the combustion chamber of the weapon was also highly instrumented with pressure transducers in an attempt to evaluate the effects of various transducer types and thermal protection greases on the magnitude of the pressure measurement. This study showed that the Kistler 6211 pressure transducer (quartz) reads about 5% higher than the E30MA pressure transducer (tourmaline) in both the forward and rear of the chamber. No conclusion could be reached as to which gage gives the more correct quasi-steady-state pressure level. In addition, the results of these tests have established this test configuration as a viable diagnostic tool that can be used for future pressure measurement phenomenology studies. Author

This paper summarizes the technical development and validation of a multiphase computational fluid dynamics (CFD) numerical method using the volume-of-fluid (VOF) model and a Lagrangian tracking model which can be employed to analyze general multiphase flow problems with free surface mechanism. The gas-liquid interface mass, momentum and energy conservations are modeled by continuum surface mechanisms. A new solution method is developed such that the present VOF model can be applied for all-speed flow regimes. The objectives of the present study are to develop and verify the fractional volume-of-fluid cell partitioning approach into a predictor-corrector algorithm and to demonstrate the effectiveness of the present innovative approach by simulating benchmark problems including the coaxial jet atomization. In order to develop more efficient rocket engines, it is necessary to have a technique to measure their mixing and combustion efficiency, both for assessing the efficiency of specific engines and for evaluating computer models of propellant mixing and combustion. This paper describes the development of an instrument that can quantitatively measure the results of incomplete mixing in rocket engines. This is done by using a novel

diode laser absorption spectroscopy technique to measure the spatial distribution of acetylene, CO, CO2, O2, or other species at the rocket nozzle exit plane. These species are characteristic of the low and high oxidizer to fuel ratio regions of the plume flowfield that result from incomplete mixing and combustion. Such spatial mapping of the nozzle exit plane has not previously been achieved for minor plume species such as acetylene that are sensitive to incomplete combustion. This instrument could be used to monitor combustion inefficiency for a wide variety of propellant types, including amine/N2O4, hydrocarbon/LOX, and LH2/LOX. The instrument development effort is currently in Phase 2 of a NASA SBIR contract. The key experimental results achieved during Phase 1 were: (1) use of a laboratory breadboard sensor to demonstrate C2H2 detection under simulated plume conditions; (2) selection and demonstration of a C2H2 absorption line that is free from significant interference by major plume species absorption lines; and (3) demonstration of C2H2 detection in an atmospheric pressure laboratory hydrocarbon/air flame. These and more recent data will be discussed in the papers, along with a description of the Phase 2 instrument that will be delivered to NASA for installation on an engine test stand. Author

DESIGN AND TESTING OF AN OXIDIZER-RICH PREBURNER **c25**

S. Farhangi, K. Hunt, L. Tuegel, and D. Matthews *In* Johns Hopkins Univ., The 31st JANNAF Combustion Subcommittee Meeting, Volume 1 Oct. 1994 p 401-408 (For primary document see N95-31194 11-28)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A full-scale oxidizer-rich liquid oxygen/gaseous hydrogen preburner article has been successfully designed, fabricated and hot-fire tested by Rocketdyne over an operating range of approximately 2000-3100 psia chamber pressure, 117-174 mass mixture ratio (MIR), and 30-50 lb/sec total propellant flow rate. Designed to minimize cost, weight, and operational complexity, the advanced oxidizer-rich preburner features direct propellant injection at a single (injector face) plane, with uniform combustion achieved in a straight length of uncooled chamber. In a series of eight mainstage tests ranging from approximately 1-5 sec in duration, the 3.5-in. diameter oxidizer-rich preburner injector repeatedly demonstrated successful ignition, flame propagation, and flameholding characteristics while achieving measured c* efficiencies of 99% with no evidence of combustion instability. Measured near wall product gas temperatures averaged from 500F (at MR = 174) to 1000F (at MR = 117), with individual thermocouple measurements falling within a 75F temperature band for each test. Through the successful hot-fire testing of a full-scale oxidizer-rich O2/H2 preburner article, a key technology enabling low-cost turbopump and full-flow staged combustion cycle (FFSC) engine design has been demonstrated. This paper describes the hardware design, fabrication, and hot-fire test results obtained in the Rocketdyne ox-rich preburner demonstration program. Author

STABILITY PREDICTION WITH ROTATIONAL FLOW EFFECTS **c25**

G. A. Flandro *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 1-26 (For primary document see N95-31282 11-28)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Time-dependent vorticity effects are incorporated in a three-dimensional combustion instability theory in this paper. Gas oscillations parallel to a burning propellant surface create waves of vorticity that modify the acoustic wave structure. The Crocco-Vazsonyi theorem shows that this oscillatory rotational flow is a consequence of the axial unsteady pressure gradient across the mean flow streamlines at the injection boundary. Viscous stresses are not important unless the ratio of frequency to injection Mach number is very high. Nevertheless, the no-slip boundary condition must be satisfied. The unsteady, rotational, closed-form flowfield solutions are in excellent agreement with cold-flow experimental data. Stability calculations with vorticity effects included yield a damping effect that is identical to Culick's one-dimensional flow-turning correction. This validates the incorporation of the one-dimensional flow-turning result in the three-dimensional, irrotational stability algorithm. However, another consequence of the no-slip requirement is a fluctuating radial flow that arises from the axial momentum defect at the injection surface. It gives rise to a flow-driving gain that cancels the flowturning loss for a full-length cylindrical propellant grain. Application of the new theory in predictive mode demonstrates much improved agreement with experimental stability data. Author

UNSTEADY LASER AUGMENTED COMBUSTION OF PURE OXIDIZERS AP AND RDX **c25**

T. B. Schroeder and M. Q. Brewster *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 27-34 (For primary document see N95-31282 11-28)

(Contract N00014-91-J-1977)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Unsteady laser augmented combustion of AP and RDX was investigated. A CO2 laser was used as an external radiant energy source to sustain AP combustion at 1 atm and to perturb the burning rate which was measured by a force transducer. Steady burning was modeled by a one-step, zeroth order decomposition process in the condensed phase. Linearized quasi-steady theory was used to model the unsteady combustion response. Both the steady and unsteady burning rate data (below 70 Hz) were reasonably well fit using E(sub c) = 2E(sub s) = 35 kcal/mole and Q(sub c) = 60 cal/g. Application of the model to RDX is also discussed.

A numerical model was developed to predict the linear and non-linear combustion response of energetic materials with condensed phase controlled burning to time-dependent incident radiation. Both surface (quasisteady) and distributed condensed phase reactions were considered. Code validation was accomplished by comparing the linear surface reaction response with the predictions of analysis (ZN or QSHOD theory). Numerical results indicated that for realistic dimensionless activation energies (greater than 5), the error in the linear response due to the quasi-steady condensed phase reaction assumption can be significant. A significant difference was also observed in the linear surface reaction response for intermediate reaction layer opacities between a constant reaction layer transmissivity, f(sub r), and a variable f(sub r). An interesting multiple-peaked non-linear response was also discovered. This multiple-peaked response was easily triggered by a pulse input. The response peaks at frequencies above that of the condensed phase thermal relaxation response appear to be caused by higher harmonics of the lower frequency components of the pulse input.

OSCILLATORY COMBUSTION OF ALUMINIZED AP/HTPB PROPELLANTS **c25**
S. R. Hickman and M. Q. Brewster *In* JHU, The 31st JANNAF Combusrion Subcommittee Meeting, Volume 2 Oct. 1994 p 51-61 (For primary document see N95-31282 11-28)

The unsteady combustion of metalized propellants was studied using the laser recoil technique. A pulsed Nd:YAG laser and a CO2 laser were used to perturb the dynamic burning rate which was measured by a force transducer. It was found that at 1 atm, certain Al/AP/HTPB propellants exhibited strong oscillatory burning between 30 and 80 Hz. This effect did not correspond to the classical solid thermal conduction-relaxation response, or QSHOD theory. These oscillations in the propellant burn rate appeared to be related to the processes of unsteady accumulation, agglomeration, ignition, and departure of aluminum at the burning surface of the propellant. The results with the CO2 laser were generally in agreement with the YAG results. A variety of AP/HTPB propellants and ingredients were tested, including aluminum, magnesium, boron, zirconium carbide, and variations in AP and Al particle size and binder concentration. Of these formulations, the ones that showed the strongest oscillatory combustion behavior were those that contained at least 15 percent aluminum and an aluminum particle size below 15 m. Flame luminosity measurements showed periodic departure of aluminum at the propellant surface at the same frequency and in phase with the burning rate oscillations. The luminosity measurements were confirmed by the use of a high speed video camera Preliminary results for the laser-driven combustion response at pressures above 1 atm were also obtained. These results, combined with the results of many control propellants, confirm that aluminum can have a much stronger influence on the combustion of AP/HTPB propellants than that indicated by the normally small changes observed in the macroscopically steady burning rate or the mean burning rate during macroscopically unsteady combustion. Scaling arguments were used to predict the frequency of the oscillations in the burn rate. Experiments showed that the frequency of the oscillations was proportional to the mean burn rate which agrees with a model based on the assumption of periodic accumulation and departure of aluminum at the surface. As prelude to the quantitative study of aluminum distributed combustion, the current work has characterized the acoustic growth, frequency, and temperature of an improved Rijke burner as a function of mass flow rate, gas composition, and geometry. Previous researchers have qualitatively studied the distributed combustion of metals in Rijke burners, but none of them have conducted a detailed investigation of their burner without particle combustion which would strengthen the relevance of their efforts. Before characterization, the burner was redesigned with an increased flow velocity of over 70 cm/s so particles will entrain. Also the flame temperature was raised to over 2400 K so aluminum particles will ignite. The burner was fitted with multiple ports for thermocouple insertion so the radial and axial temperature profiles could be quantified which is crucial for parallel efforts to model the Rijke burner. The flame's position relative to the burner's acoustic driving regions along with the temperature profile primarily determined which mode would be driven and the magnitude of that acoustic driving. By varying the exhaust temperature profile, the acoustic growth rate can be as much as tripled from the baseline value of approximately 120 s(exp -1). At baseline, the burner operated in the third harmonic mode at a frequency of 1300 Hz, but geometry or temperature changes could shift operation to a second mode. During oscillatory combustion, centerline temperatures in the exhaust rose by as much as 80 K when compared to the non-oscillating case. With oscillations, the mean flow of gases in the boundary slowed with a consequent decrease in heat transfer to the walls. The information gained in this study will aid in refining burner modeling efforts and allow interpretation of planned aluminum combustion studies in hopes of gaining a greater understanding of distributed combustion as a driving mechanism in the combustion instability of solid propellant rocket motors. Active control of solid propellant combustion oscillations in a T-burner by properly timed, pulsed chemical injection was investigated. The principal purpose was to demonstrate a realistic active control mechanism that could be applied to solid rocket motors. Active injection control would be especially applicable to large booster systems and motors where conventional methods of suppressing instabilities cannot be used. This paper describes the experimental strategy, the results obtained and future plans. Author

A meanline pump flow modeling method has been developed to provide a fast capability for modeling pumps of cryogenic rocket engines. Based on this method, a meanline pump flow code PUMPA has been written that can predict the performance of pumps at off-design operating conditions, given the loss of the diffusion system at the design point. The design point rotor efficiency and slip factor are obtained from empirical correlations to rotor specific speed and geometry. The pump code can model axial or inducer, mixed-flow and centrifugal pumps. The code can model multi-stage pumps in series. The rapid input setup and computer run time for the meanline pump flow code makes it an effective analysis and conceptual design tool. The map generation capabilities of the code provides the information needed for interfacing with a rocket engine system modeling code. The off-design and multi-stage modeling capabilities of the code permit the user to do parametric design space exploration of candidate pump configurations and provide head-flow maps for engine system evaluation. MODEL FOR DEFINING PROPELLANT BURN RATE PERFORMANCE BOUNDARIES **c25**
W. M. Fisher and R. R. Miller *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 123-131 (For primary document see N95-31282 11-28)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A method for formulating solid rocket propellants with a constant burn rate has been developed. The method uses a model, which predicts burn rate for a particular ammonium perchlorate size distribution, to search the particle size space to identify the region which gives the desired burn rate. The model used to predict the burn rate was put forward by Kerstein. It defines burn rate in terms of an ideal rate for a binder-ammonium perchlorate system, that is modified to account for over or under oxidation. The ideal burn rate was expressed in terms of a modified Springfield relationship. The modifier is a scaling function which equals one at the optimum fuel/oxidizer ratio and decays as the ratio deviates from the optimum. The procedure has been used to develop an applied propellant formulation, by

defining ammonium perchlorate size distributions which possessed a constant burn rate. The candidate formulations then were optimized for processibility. Author

The continuing need for advanced solid propellants during these times of great change within the propulsion industry is creating a need for improved developmental methods. The Johns Hopkins University, Chemical Propulsion Information Agency is acting as a catalyst to document common practices and standardized methods used within the U.S. propulsion industry to measure solid propellant burning rate. This work has guided the early planning stages for a working group of the Advisory Group for Aerospace Research and Development (AGARD), Propulsion and Energetics Panel (PEP). The scope of the AGARD/PEP working group is to arrive at a consensus on consistent burning rate measurement methods for the participating NATO nations. The experience base of years of solid propellant development and advances in non-intrusive diagnostics applied to burning rate measurement technology are thought to provide opportunities to contribute to the affordability, accuracy, and reliability of the future solid propellant data base. A review is presented of standardized methods and current experience base within the U.S. gun and solid rocket propulsion industry for measuring propellant burning rate. Industry trends in methods used and the degree of uniformity and standardization are identified. Results indicate how facilities are responding to the changing state of the propulsion industry. These results also served to guide the focus of the AGARD/PEP working group toward (1) solid propellant burning rate measurement by small/subscale motor methods, and (2) solid propellant burning rate measurement by non-intrusive techniques. Future activities include the updating and expanding of JHU/CPIA's national reference manuals on propulsion to include facilities to measure solid propellant burning rate; planning and conducting a JANNAF workshop in 1995 on the current state and advances in U.S. solid propellant burning rate measurement methods; and initiating the AGARD/PEP working group in late 1995. AN IGNITION MODEL FOR MODERN DOUBLE BASE PROPELLANTS c25

M. W. Beckstead *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 163-180 Sponsored in cooperation with LMSC (For primary document see N95-31282 11-28)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A computer code has been developed for predicting the ignition characteristics of modern double base propellants in a motor environment. The code is based on the NWC ignition code developed by Price of the NAWC. The physical model is based on the characteristics of the combined ingredients of typical energetic propellants: HMX, AP, a nitroglycerin based binder, and aluminum. The fundamental equation in the model is the transient heat conduction equation for the solid. It is assumed that a single averaged equation adequately describes the propellant. Each ingredient (HMX, AP, and NG based binder) is assumed to react through two condensed phase reactions and a gas phase or flame reaction. From these equations the model predicts a time to ignition and a steady burning rate. Care was taken to ensure that the ignition process transitions smoothly to the combustion process. A disadvantage of previous ignition codes has been the determination of the various combustion parameters in a model. Various schemes have been used to arrive at realistic values. In the current approach, activation energies are taken from the literature wherever possible. This ensures the use of realistic kinetic parameters in the calculations. The computer code has most of the required physical, thermochemical and kinetic parameters built into it and uses rational techniques to average these properties to correspond to an input propellant formulation. Using this approach, all of the propellant properties, including physical, chemical and kinetic, are inherent to the code. This greatly simplifies the input task for a typical user. Validation of the computer code was achieved by making calculations for each of the three principal ingredients and comparing those calculations to available data. The primary comparisons were made between calculated and experimentally measured burning rates and ignition times. Comparisons were also made between calculated and experimentally measured surface temperatures. The agreement between the calculations for HMX, AP and double base binder and the available data was very reasonable. Calculations have also been made for a typical propellant containing 51% HMX, 19% aluminum, 5% AP and 25% binder. Ignition times of approximately 10 msec were calculated for flux levels of approximately 100 cal. The model predicts that the ignition time should decrease with increasing heat flux and should increase with decreasing pressure, which are the observed trends. Author

MOLECULAR MODELS FOR NITRO COMPOUNDS

George F. Adams, Betsy M. Rice, and Cary F. Chabalowski *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 181-184 (For primary document see N95-31282 11-28)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

This paper summarizes our recent research to extend the applicability of molecular modeling and molecular dynamics computational methods in the area of energetic materials chemistry and physics. We describe progress in the extension of a molecular forcefield that includes parameters that enable the researcher to include nitro compounds of several types. The evolution of methods for deriving the forcefield is briefly discussed, and we suggest a variety of molecular modeling applications that may benefit from this approach to forcefield derivation. In addition, we describe the classical simulation of the decomposition paths accessible to methylene nitramine. The chemical rates and mechanisms of the two primary decomposition channels are presented. The classical barrier heights for the two dominant decomposition channels: (a) N-N bond scission to form CH2N and NO2, and (b) concerted dissociation via a five-center transition state, differ by 2 kcal/mol. A new method for estimating heat of formation (HF) of energetic compounds has been developed. This method is based on the AM1 semiempirical molecular orbital method. The AM1 method generally does well at predicting HF for organic compounds. However, this method does poorly at estimating HF for energetic compounds containing nitro groups. Using statistical methods, a systematic correction to the AM1 method has been developed for nitro compounds. This correction brings AM1 HF predictions for energetic compounds into agreement with experimental data. This method offers an independent check on HF predicted using other methods. The method should be particularly useful in predicting HF for caged compounds. Author

Samples of gun propellants that have been self-extinguished at low pressures have been examined under a scanning electron microscope; the results suggest that the surface Layers consist of a thin layer of binder

and decomposition product, above a thicker layer of crystalline material that is presumably mostly solidified (liquefied during combustion) RDX oxidizer. Photoacoustic FTIR spectra of some burned/extinguished samples of XM39, JA2 and RDX are also reported and discussed. Author

It is generally known that a surface reaction zone exists on the burning surface of nitramine propellants at pressures less than 6.87 MPa (1000 psia). Although this layer is acknowledged to play an important role in the combustion process, the detailed structure remains relatively uncharacterized due to variations with propellant formulation and operating conditions and the difficulty of instrumentation under combustion conditions. Using a high-magnification imaging system, in situ surface phenomena were observed on 0.64 cm (0.25 in) diameter samples of RDX, the nitramine composite propellants XM39 and M43, and a triplebased propellant JA-2 over a pressure range of 0.10 MPa (0 psig) to 3.55 MPa (500 psig). At atmospheric pressure, RDX formed a thick bubbling foam layer up to 650 mu m thick. The thickness of the layer quickly decreased with increase in pressure, but the layer was present at all conditions tested. Liquid layers of XM39 and M43 were similar in appearance with small mobile carbonaceous particles in the liquid layer that agglomerated into flame-holding sites at higher pressures. The pressure at which the liquid layer disappeared was lower for M43 than that for XM39. Carbonaceous residues were important as sites for flame attachment to the surface on all propellants tested. MODELING OF THERMAL RESPONSE OF FILAMENT USED IN T-JUMP EXPERIMENT c25
Stefan T. Thynell, Polly E. Gongwer (Delaware Univ., Newark, DE.), and Thomas B. Brill (Delaware Univ., Newark, DE.) *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 221-232 (For primary document see N95-31282 11-28)
(Contract DAAL03-92-G-0118)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

During the combustion of solid propellants, explosives or pyrotechnics, the condensed phase experiences heating rates that may exceed 20,000 K/s. At such high heating rates, the thermal decomposition behavior of the energetic material could be affected by its rate of decomposition. To simulate the high heating rate environment, the T-jump experiment was developed for use with FT-IR spectroscopy. The T-jump experiment utilizes electrical resistance heating of a thin Pt filament on which a small amount of the energetic test sample is placed. This work describes a heat transfer model of the filament and sample, a model of the current's control circuit, and global decomposition and heat release mechanisms of RDX, which is an energetic ingredient used in propellants and explosives. Comparisons of model calculations with experimental data reveal an excellent agreement. Similarly, the predicted time to rapid heat release for the highly energetic RDX sample also show a good agreement with experimental results. Thus the use of the developed model in conjunction of with experiments should be a useful tool in studying the thermal decomposition behavior of energetic materials under combustion-like conditions. A method was developed for measuring the dynamic mass loss rate during laser pyrolysis of polymeric binder materials. This method was applied to an investigation of the thermal decomposition of hydroxyl-terminated polybutadiene (HTPB). A technique was developed for measuring the laser plume transmission loss during laser pyrolysis. Microthermocouple measurements of the surface temperature were also performed. The effective sample heating rate ranged from 10(exp 2) to 10(exp 4) K/s. A zeroth order global condensed phase decomposition model was used to fit the measured data and extract kinetic and thermochemical parameters. The kinetic parameters agreed well with Chen and Brill's SMATCH/FTIR results measured at 250 to 350 K/s while the heat of decomposition agreed with that of Cohen, et al. It was also found that the presence of one percent carbon black in HTPB lowered the regression rate by at least 30 percent. Author

Under transient conditions, the instantaneous burn rate of solid propellants may differ significantly from the steady-state value. Any instantaneous burn rate difference caused by rapid pressurization may introduce in the performance prediction of gun propulsion systems. With this as motivation, research has been performed on a commonly used triple-base gun propellant, JA-2, to determine the effect of large pressure excursions on instantaneous burning rate. Transient burning rate tests were conducted using an interrupted burner with x-ray translucent windows that permit observation of the propellant samples during the transient event. The interrupted burner also allows the propellant samples to be recovered from within the chamber after rapid depressurization terminates combustion. The instantaneous burning rates of JA-2 propellant rods were determined using two techniques. The first technique utilized real-time x-ray radiography images to deduce the instantaneous change in diameter for each propellant rod. The second technique utilized a modified interior ballistic burn rate analysis code that took advantage of the propellant sample recovery feature of the interrupted burner. The instantaneous burning rates deduced from both of the analysis techniques were compared to the steady-state burning rate values, obtained using an optical strand burner, in order to assess the degree of dynamic burning. For JA-2 propellant rods subjected to high pressurization rates (dp/dt less than 11,000 MPa/s), departure from the steady-state burning rate was found to be small. This observation was explained using the stability theory of Novozhilov with measured temperature sensitivity and best estimated surface temperature variation with chamber pressure. Author

The antibiotic azomycin is 2-nitroimidazole. 2,4-dinitroimidazole has recently been found to be a fairly powerful yet stable explosive. The family of all nitro substituted imidazoles constitute an interesting series of molecules from both the biological and the energetic material points of view. Imidazole is a heterocyclic five membered ring with two nitrogen atoms in the ring. One of these nitrogens is bound to a hydrogen atom so that it can act as a proton donor. The other nitrogen can act as a proton acceptor. The molecule can therefore act as both an acid and a base. In this work the protonation and deprotonation energies for all the nitro substituted imidazoles are computed with several basis sets. The GAUSSIAN 92 set of programs is used and all computations are performed at the SCF level of theory. The geometry of all the structures are determined using gradient techniques and compared to experimentally obtained geometries when available. It is found that these materials become more acidic and less basic as the degree of nitration increases. Author

MEASUREMENT OF TEMPERATURES AND OH CONCENTRATIONS OF SOLID PROPELLANT FLAMES USING ABSORPTION SPECTROSCOPY c25

Yeu-Cherng Lu, Todd Freyman, and Kenneth K. Kuo *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 277-290 (For primary document see N95-31282 11-28)
(Contract DAAL03-92-G-0118)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Multi-parameters least-squares analysis of rotationally resolved absorption spectroscopy in the Alpha(sup 2)Sigma(sup 2)-Chi(sup 2)Pi (0,0) vibrational band system of OH from 307 to 311 nm was performed to determine the flame temperatures and OH concentrations of JA-2 double base propellant under steady-state burning at elevated pressures with a spatial resolution of 50-100 micrometers. Deduced flame temperatures were 2754 +/- 124 K, 2836 +/- 147 K, 2852 +/- 179 K, and 2873 +/- 188 K at pressures of 1.60, 3.55, 5.62, and 6.99 MPa, respectively; the corresponding OH number densities were (1.09 +/- 0.34) x 10(exp 17), (2.31 +/- 0.48) x 10(exp 17), (3.31 +/- 0.27) x 10(exp 17), and (3.44 +/- 0.30) x 10(exp 17) molecules/c.c., respectively. The results at 1.60 MPa agree well with data in the literature, and deduced flame temperatures at high pressures agree well with chemical equilibrium calculations. OH mole fractions are about 40 percent lower than the equilibrium analysis. This work represents the first set of optical absorption measurements performed on solid propellants at pressures above 2.0 MPa. Author

SPECIES AND TEMPERATURE PROFILES OF PROPELLANT FLAMES OBTAINED FROM FTIR ABSORPTION SPECTROSCOPY c25

C. F. Mallery and S. T. Thynell *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 291-305 (For primary document see N95-31282 11-28)
(Contract DAAL03-92-G-0118)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The use of Fourier transform infrared (FTIR) absorption spectroscopy to obtain species and temperature profiles within solid-propellants flames is described in this paper. Measurements were performed at a spectral resolution of 4 cm(exp -1) and a spatial resolution of 1 mm within the flame-zone of two nitramine composite propellants. A nonlinear, least-squares routine fitted the experimentally acquired absorption spectra to theoretical spectra which yielded a prediction of the absolute species concentrations of CO, NO, H20 and CO2 as well as the rotational temperature. Line-of-sight deduced temperature profiles for XM39 and M43 propellants showed dark-zone/luminous flame-zone structures for both propellants. The mole fraction of CO increased while the mole fraction of NO decreased from the beginning of the dark-zone to the luminous flame zone. Data on the spatial variation of species concentration and temperature within the flame zone are important for the development and validation of chemical kinetic mechanisms of these solid propellants. A STUDY OF GAS-PHASE PROCESSES DURING THE DEFLAGRATION OF RDX COMPOSITE PROPELLANTS USING A TRIPLE QUADRUPOLE MASS SPECTROMETER c25

Ching-Jen Tang, Young Joo Lee, and Thomas A. Litzinger *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 307-316 (For primary document see N95-31282 11-28)
(Contract DAAL03-92-G-0118)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Measurements of chemical species were obtained in a study of RDX composite propellants, XM39 and M43 as well as binders, Cellulose Acetate Butyrate (CAB) and Acetyl Triethyl Citrate (ATEC). Experiments were conducted in an argon environment and a CO2 laser was used to initiate and sustain reaction of the propellants. Measurements of species were conducted at a pressure of one atm, with heat fluxes of 100 and 400 W/cu cm, cc. Gas samples were extracted using a quartz microprobe and analyzed using a triple quadrupole mass spectrometer (TQMS). The TQMS is capable of resolving species which could contribute on the same masses: CO, C2H4 and N2 to mass 28, and CO2, CH3CHO and N2O to mass 44. Using the parent and daughter modes of the TQMS and careful calibration, it was possible to identify and quantify these species. Both materials exhibited similar gas phase reaction chemistry at one atm and heat fluxes of 100 and 400 W/cm. The major species at the surface were NO2, CO2, CH2O, NO, N2O, HCN and H2O for XM39 and M43. Species at 44 amu were mainly N2O and CO2, while species at 28 amu were composed primarily of CO and N2. The measurements also also revealed that the primary flame zone was 3.5 mm for XM39 and 2 mm for M43. The results indicated that the reaction zones for both materials were significantly stretched out in comparison to that for RDX mono-propellant. The most notable difference between RDX mono-propellant and both RDX composite propellants was in the absence of CH2O observed by Lee. These results indicated that the primary flame of both propellants formed by the reaction of CH2O and NO2 was different from that of RDX. CAB and ATEC were studied at one atm and a heat flux of 100 W/cu cm, cc. Species at molecular weights of 60, 44, 43, 42, 28, 29, 73 and 41 for CAB and 57, 56, 43, 91, 92, 45, 41 and 31 for ATEC were detected by TQMS. The daughter spectra revealed that the major contributors for CAB were large hydrocarbons, CO2 and CO. Author

EMBEDDED INFRARED FIBER OPTIC ABSORPTION STUDIES OF NITRAMINE PROPELLANT STRAND BURNING c25

J. Wormhoudt and P Kebabian, L. *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 317-324 (For primary document see N95-31282 11-28)
(Contract DAAH04-93-C-0053)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

This paper reports on continued work to develop and demonstrate the use of infrared fiber optics to probe the decomposition processes in burning gun propellant strands. Our experiments involve measuring the absorption across an open gap between two embedded fibers as it fills with gaseous decomposition products. Several improvements have been made to the experimental technique. In the most significant, a visible detection system for NO2 based on differential absorption by red and green HeNe lasers has been added to the N2O detection system using two infrared bandpass filters described previously. As with N2O, we have observed NO2 evolving into the observation volume during the burning of an RDX-based composite propellant. Observations to date indicate that NO2 appears simultaneously with N2O, that is, while the observation region is relatively cool and far from the burning surface. More observations will be required before we can be sure there are no significant differences in the time history of the evolution of the two gases. These data will provide additional information on the physical and chemical processes in the condensed phases of this composite propellant, including the development of pressurized voids or matrix-trapped bubbles which can release decomposition gases into unburned propellant through suddenly opening cracks. IMPROVEMENTS IN INFRARED ABSORPTION OF SOLID PROPELLANT FLAMES c25
S. H. Modiano and J. A. Vanderhoff *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 325-332 (For primary document see N95-31282 11-28)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Last year we reported the first application of a multichannel infrared absorption technique for the study of the dark zone of solid propellant flames. This year we report improvements in the technique which include an increase in the data acquisition rate by a factor of five, the ability to sequentially acquire an emission spectrum for each absorption spectrum during the acquisition cycle, the ability to correct for any emission background which may distort the absorption spectrum, and better compensation for the underlying broadband absorption feature thought to be due to soot formation. The improved instrument has been used to obtain dark zone measurements for two nitramine propellants (M43 and XM39). From these measurements and the HITRAN database concentration and temperature estimates for HCN, H2O, CO, CH4, H2CO, and N2O have been determined. It is shown that a single temperature model may be inadequate for simulating the H2O features in the observed spectra. Author

The diffusion flame structure of sandwich geometry propellants made from HMX, TNAZ, AP, ADN (Ammonium Dinitramide), and a variety of polymers including wax, HTPB, N5, and various high energy binders including some based on GAP and BAMO/NMMO, was studied using Planar Laser Induced Fluorescence (PLIF) and Mie scatter imaging for sandwiches deflagrating at pressures between 1 and 20 atm. Flame species imaged as two dimensional profiles included CN, OH, and NO (v=0 and v=1). Two dimensional gas temperature profiles were obtained from OH rotational and NO vibrational population distributions. Various lamina thicknesses were studied down to a binder layer thickness of 50 mu m. Neat TNAZ was found to be much harder to ignite than HMX or RDX and to self deflagrate with a visible flame only at pressures above 8 atm. Under these conditions the hot flame is very close to the surface. The combination of either HMX or TNAZ with HTPB, N5, or energetic binders produced no evidence of a diffusion flame: the binder decomposition products slowed the nitramine dark zone kinetics in the diffusion mixing fan coming from the interface and caused the nitramine secondary flame to standoff higher from the surface than normal. In sharp contrast, the combination of HMX or TNAZ with either AP or ADN lead to obvious diffusion flame interactions: the AP or ADN decomposition products accelerated the nitramine dark zone kinetics and caused the secondary flame height to drop significantly from it's normal height. This lead to higher heat feedback in the interface region and a somewhat faster nitramine regression rate. The ammonia (and other amine) products from the AP or ADN decomposition probably speed the reduction of NO thereby accelerating the nitramine dark zone reactions. Author

AN ab Initio STUDY OF THE REACTION HNO+NO YIELDS OH+N2O: PRELIMINARY RESULTS c25
Steven W. Bunte, Cary F. Chabalowski, and Betsy M. Rice *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 345-354 (For primary document see N95-31282 11-28)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The reaction of HNO with NO to produce N20 and OH has been studied by ab initio molecular orbital calculations. Preliminary results indicate that there are two distinct pathways that lead to products, however, only one is energetically favorable. The first reaction path begins with N-N association and forms a cis ONNO intermediate before encountering a 66 kcal/mole barrier, thus effectively halting the reaction. The second pathway also begins with N-N attack, this time however in a trans ONNO arrangement. While not complete at this writing, this pathway appears to be the first substantiation of an energetically viable pathway for this reaction. Author

Kinetics experiments on mixtures of CO/N2O/H2O/N2 were performed in a variable pressure flow reactor at three atmospheres and temperatures near 1100 K. Experimentally measured profiles of CO, CO2. O2, H2O, N2O, NO and temperature were compared with modeling predictions obtained from a detailed chemical kinetic mechanism. At these conditions, the direct reaction of carbon monoxide with nitrous oxide results in at most 10 percent of the observed CO2 formation. The overall reaction rate is strongly affected by background water concentrations. Refinements in the current C/H/N/O kinetic mechanism are still incapable of precisely predicting these experimental data. Reaction flux and sensitivity analyses were used to identify the rate controlling reactions. For the first time, the individual catalytic effect of water vapor is clearly evident and a quantitative treatment of its influence is now possible. Author

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The kinetics of dilute CO/NO2/H2O mixtures have been studied in a flow reactor at temperatures of 773 K and 873 K, equivalence ratios near 10, and a pressure of 9 atm. Concentrations of NO2, NO, CO, CO2, and H2O were measured, providing a highly constrained set of reactant and product profiles as a function of time. These were compared to profiles from an evolving detailed kinetic model, using reaction flux and sensitivity analyses to identify rate controlling reactions. These first experiments, detailing the effects of water on the NO2/CO system, show a strong rate dependence on the water concentration. In direct contrast to the experimental results, the model predicts very little effect from water, and a reaction rate significantly slower than the experimental rate, even in experiments with low background water concentrations. DETAILED CHEMICAL KINETIC MODELING OF PREMIXED HYDROCARBON FLAMES SUPPORTED BY NO2 c25
Bradley A. Williams and James W. Fleming *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 377-386 (For primary document see N95-31282 11-28)
(Contract N00014-94-WX-2D001)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Efforts to model the chemical structure of premixed flames of various hydrocarbon fuels supported by NO2 are presented and compared to available experimental data. The flames investigated include CH2O/NO2/O2, CH4/NO2/O2, HCN/NO2, C2N2/NO2, and C2H2/NO2. Structures of flames of C fuels are generally well predicted by current reaction sets, but the acetylene/nitrogen dioxide flame cannot be accurately modeled. The principle cause of this is postulated reactions of NO and NO2 with various species containing two carbon atoms whose rates are either completely unknown or have only been measured for a very limited set of conditions. Flame systems and individual reactions for which further study is needed are discussed. Author

STUDIES OF REACTIONS PERTAINING TO AND DEVELOPMENT OF A REDUCED MECHANISM FOR THE DOUBLE BASE PROPELLANT DARK ZONE **c25**
W. R Anderson, N. Ilincic (California Univ., La Jolla, CA.), and K. Seshadri (California Univ., La Jolla, CA.) *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 387-397 (For primary document see N95-31282 11-28)
(Contract DAAL03-90-G-0084)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Efforts to develop a detailed mechanism describing the chemical kinetics and structure of the dark zone of double base propellants are discussed. The detailed mechanism has been developed and first reduced in several steps to a skeletal mechanism of elementary steps consisting of 43 reactions amongst 16 species. It is then discussed how this mechanism has been further reduced by four species using steady state assumptions. This reduction involves usage on a homogeneous ignition delay type of problem and is the first of its kind, demonstrating that viable reduced mechanisms indeed can be produced for such ignition delay applications. In the development of the detailed mechanism, a very important consideration was the proper rate coefficient to use for N2O + O = NO + NO. Detailed modeling calculations of the shock tube experiments which have led to very high values in the literature for the rate coefficient of this reaction are shown to have been seriously affected by an incorrect assumption that the reaction H + N2O = NO + NH may be neglected. This and other key reactions in the development of the detailed mechanism are discussed. Author

State-of-the-art combustion diagnostics and advanced computational tools, developed at the Army Research Laboratory, have been applied to studies of the detailed flame chemistry relevant to the gaseous flames of burning energetic materials. The experimental results provide the necessary validation for combustion models that are being developed to simulate energetic material combustion for increased system performance. In this paper, we report a combined experimental and detailed kinetic modeling study on neat and NH3-doped H2/N2O burner stabilized flames in order to understand the fundamental mechanism for NO formation and destruction, and to determine and predict the efficacy of NH(x) additives on rate of conversion of NO to the final product N2. NO is an environmental pollutant and a product of incomplete combustion (PIC). In many systems, including propellants and explosives, it acts as a chemical inhibiter, thus preventing full energy release. This system was chosen because it has important implications in understanding nitramine propellant combustion and decomposition, and NO(x) pollutant formation during demilitarization operations. Species concentration and temperature profiles were obtained using molecular beam mass spectrometry and thin-wire thermocouples, respectively. Species profiled include H2, N2O, NH3, Ar, H2O, N2, O2 and NO. These profiles are compared to calculated profiles generated using PREMIX, a one dimensional premixed laminar flame code. The detailed chemical mechanism employed in the code consists of 88 reactions and 20 species, and was derived from preliminary calculations using a more comprehensive set of reactions (greater than 200) obtained from a critical literature review. Our experimental results show that the addition of small amounts of NH3 reduces significantly the NO concentration, e.g. a 50 percent reduction for a 4 percent NH3 addition. This result is also borne out in our model calculations. Rate and sensitivity analyses were performed on the PREMIX results using an interactive postprocessing code we have written so that the details of the chemistry may be understood. Applications of these results for better propellant formulation and increased performance are also discussed. Author

RDX LASER-ASSISTED FLAME STRUCTURE **c25**
Donna Hanson-Parr and Tim Parr *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 407-423 (For primary document see N95-31282 11-28)
(Contract N00014-92-WX-24097)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

UV-Visible absorption measurements have been done in RDX flames to obtain concentrations of NO, NO2, CN, OH, and RDX using different laser fluxes and then compared with those obtained for the steady state (no laser) case. For the CO2 laser fluxes used, it was found that the NO and NO2 species profiles, scaled to the CN radical flame height, were very nearly the same, except that both were low if the flux was not high enough. This showed that a laser could be used to stretch out the flame to improve spatial resolution of measurements and validate the results obtained. The (OH) concentration in the burnt gas region appeared to be the same for all laser fluxes, but the (CN) apparently increased. Burning rates as a function of laser flux were also obtained and were linear with flux except at the low end where the heat feedback produced under steady state conditions became comparable to the external laser flux, as evidenced by the similar CN flame standoff distance. Other results showed that the mole fraction of H2CO coming off the surface is below 1 percent even at heating rates very much lower than what the RDX would see in a deflagrating rocket propellant, but may be as high as 7 percent in the 'melt' layer. It was observed that RDX smoke is formed prior to ignition and an interesting, but as yet unassigned, structured absorption band in the 320 - 400 nm region, not due to formaldehyde, HONO, NO2, or atomic absorption, is clearly visible and was not seen in HMX smoke. Particle imaging velocimetry was used to obtain a velocity vector field of a laser-assisted flame and showed that the centerline velocity was essentially constant at 5.5 m/s through the dark zone and secondary flame. A STUDY OF THE GAS-PHASE PROCESSES OF RDX COMBUSTION USING A TRIPLE QUADRUPOLE MASS-SPECTROMETER **c25**
Young Joo Lee, Ching-Jen Tang, and Thomas A. Litzinger *In* JHU, The 31st JANNAF Combustion Subcommittee Meeting, Volume 2 Oct. 1994 p 425-437 (For primary document see N95-31282 11-28)
(Contract N00014-93-1-0080)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Measurements of gas-phase chemical species were obtained in an RDX mono-propellant flame to study key chemical processes. Experiments were conducted in an argon environment and a high-power CO2 laser was used to initiate and sustain combustion. Measurements of species were conducted over a pressure range of 0.1 to 3 atm, and at several heat fluxes over the range of 50 to 600 W/cm (exp 2). Gas samples were extracted using a quartz microprobe and analyzed using a triple quadrupole mass spectrometer (TQMS). The TQMS is capable of resolving species which could contribute on the same mass: N2 and CO to mass 28; N2O and CO2 to mass 44. This capability was also applied to differentiate NO and CH2O at mass 30, and to identify species other than CHO present at mass 29. Using parent and daughter modes of the TQMS and careful calibration, it was possible to differentiate and quantify many of these species. For the experimental conditions selected, the major species at the surface were NO, HCN, H2O, N2O, CO, NO2 and mass 29. The ratio of (N2)/(CO) is approximately 1.5 at the surface, and decreased to about 1.0 at the end of the luminous flame zone at mass 28. Mass 44 totally consisted of N2O at the surface without CO2, and the portion of N2O decreased exponentially to 0 at the end of reaction zones, while the reverse trend was true for CO2. At 1 atm and a heat flux of 100 W/cm (exp 2), near the surface, NO turned out to constitute the majority of mass 30, and only small amount of CH2O was identified. As identified by the species profiles of HCN, NO and N2O, the reaction zones expanded as heat flux increased and pressure decreased. Even with the expansion of reaction zones, no evidence of the near surface-reaction zone was found. Author

PROCEEDINGS OF THE HIGH ENERGY DENSITY MATTER (HEDM) CONTRACTOR'S CONFERENCE Special Report
T. L. Thompson and S. L. Rogers Dec. 1994 308 p Conference held in Crystal Bay, NV, 5-7 Jun. 1994
(AD-A292988; PL-TR-94-3036) Avail: CASI HC A14/MF A03

This report documents the information presented at the eighth annual High Energy Density Matter (HEDM) Contractors' Conference held 5-7 June 1994 in Crystal Bay, NV. This report contains the extended abstracts of the oral, workshop, and poster presentations given by the Air Force funded contractors and by the in-house researchers from the Phillips Laboratory. The main purpose of the High Energy Density Matter (HEDM) program is to research and develop advanced high energy compounds containing increased energy densities (energy to mass ratios) to produce greater specific impulses (thrust per weight flow rate of propellant) which will enable spacecraft to carry larger payloads. With these advanced propellants, future space-bound payloads could be possibly four times greater that they are today. DTIC

ACIDITY AND BASICIDITY OF NITRO SUBSTITUTED IMIDAZOLES
T. Vladimiroff Apr. 1995 16 p
(AD-A293969; ARAED-TR-94-021) Avail: CASI HC A03/MF A01

The antibiotic azomycin is 2-nitroimidazole. 2,4-dinitroimidazole has recently been found to be a fairly powerful yet stable explosive. The family of all nitro substituted imidazoles constitute an interesting series of molecules from both the biological and the energetic material points of view. Imidazole is a heterocyclic five membered ring with two nitrogen atoms in the ring. One of these nitrogens is bound to a hydrogen atom so that it can act as a proton donor. The other nitrogen can act as a proton acceptor. The molecule can therefore act as both an acid and a base. In this work the protonation and deprotonation energies for all the nitro substituted imidazoles are computed with several basis sets. The GAUSSIAN 92 set of programs is used and all computations are performed at the SCF level of theory. The geometry of all the structures are determined using gradient techniques and compared to experimentally obtained geometries when available. It is found that these materials become more acidic and less basic as the degree of nitration increases. DTIC

THE PHYSICAL AND CHEMICAL PROCESSES GOVERNING CO2 LASER-INDUCED PYROLYSIS AND COMBUSTION OF THE SOLID PROPELLANTS RDX, ADN, XM39, AND M43 Ph.D. Thesis
Barry Lynn Fetherolf 1993 238 p
Avail: Univ. Microfilms Order No. DA9414276

CO2 laser-induced pyrolysis and combustion of RDX, XM39, M43, and ammonium dinitramide (ADN) were investigated experimentally and by kinetic modelling. Gas species and temperature profiles as a function of measuring height, laser heat flux, and pressure were measured with a microprobe/mass spectrometer system and fine-wire thermocouples. Gas phase processes for RDX and ADN were modelled with CHEMKIN as a 1-D, premixed flame. Three distinct categories of laser-induced behavior were observed: laser-induced pyrolysis (LIP) characterized by decomposition without stable surface regression, laser-induced regression (LIR), and laser-assisted combustion (LAC), the latter two categories characterized by stable regression of the surface but with a luminous flame only observed for LAC. Under LIP conditions, RDX exhibited a thick melt layer with considerable bubbling. Gas species within a bubble were measured with the most abundant species being CH2O, H2O, NO2, and N2O. Species profiles for RDX at 0.5 and 1.0 atmospheres under LAC conditions were measured. Reaction of CH2O and NO2 occurred directly above the surface followed by a final luminous flame due to reaction of HCN, NO, and N2O. The kinetic model for RDX produced excellent agreement between model and experimental species profiles. Both XM39 and M43 exhibited the same overall reaction chemistry as pure RDX but displayed distinctly different laser-induced behavior. M43 exhibited a higher surface temperature and less CH2O and NO2 at the surface than XM39, possibly due to increased condensed phase reaction. XM39 did not exhibit LAC until five atmospheres whereas M43 required a pressure of only three atmospheres to achieve LAC. ADN pyrolyzed and burned roughly an order of magnitude faster than the other propellants. Under LIR conditions, ADN evolved N2O, H2O, N2, NO2, and NH3 in order of decreasing mole fraction, and numerous particles of ammonium nitrate. LAC was observed for ADN at three atmospheres with an unstable flame whereas tests at five atmospheres produced a more stable flame with individual flamelets just above the surface. The flame produced significant amounts of NO and H2O and a gas temperature of about 1350 K. Dissert. Abstr.

NATURAL GAS LIQUEFIER FOR VEHICLE FUEL Interim Report, Jan. - Dec. 1994
E. C. Owens and K. Randall Kohuth (General Pneumatics Corp., Scottsdale, AZ.) Mar. 1995 86 p
(Contract DAAK70-92-C-0059)
(AD-A293619; TFLRF-310) Avail: CASI HC A05/MF A01

This project was a continuation and refinement of a feasibility prototype natural gas liquefier that had been designed, fabricated, and tested under a U.S. Department of Energy (DoE) Small Business Innovation Research (SBIR) contract. Extensive performance testing was conducted to characterize the natural gas liquefier refrigeration capability and to collect data for diagnostic purposes. Analysis of the effectiveness of the regenerator concluded that the current design would require substantial empirical iterations. The final prototype with a design target of 1,000 Watts (W) refrigeration was able to achieve only 400 W of refrigeration, projected to 550 W at a higher charge pressure. Recommendations are made for further testing, analysis, and correlation to achieve a better optimized regenerator design for a second generation prototype natural gas liquefier. DTIC

(DE95-010304; NREL/SP-420-5572-Rev-2) Avail: CASI HC A01/MF A01

Ethanol from biomass is a domestically produced liquid fuel from renewable, virtually inexhaustible domestic resources. It is a nonfossil transportation fuel that contributes little, if any, net carbon dioxide to the atmosphere during production and use. It is a high-octane fuel that can contribute substantially to the US automotive fuel supply. It is a fuel that can be used as a blend, a component of ethyl tertiary butyl ether (ETBE), or as a pure fuel, with excellent efficiency and performance. It is a potentially clean-burning fuel that reduces smog and emissions of carbon monoxide. This overview presents the resource potential, processing techniques, DOE program highlights, utilization potential and environmental effects of ethanol from biomass. DOE

Base hydrolysis in combination with hydrothermal processing has been proposed as an environmentally acceptable alternative to open burning/open detonation for degradation and destruction of high explosives. In this report, the authors examine gaseous and aqueous products of base hydrolysis of the HMX-based plastic bonded explosive, PBX-9404. The authors also examine products from the subsequent hydrothermal treatment of the base hydrolysate. The gases produced from hydrolysis of PBX-9404 are ammonia, nitrous oxide, and nitrogen. Major aqueous products are sodium formate, acetate, nitrate, and nitrite, but not all carbon products have been identified. Hydrothermal processing of base hydrolysate destroyed up to 98% of the organic carbon in solution, and higher destruction efficiencies are possible. Major gas products detected from hydrothermal processing were nitrogen and nitrous oxide. DOE

THERMOPLASTIC ELASTOMERS AS A BINDER IN COMPOSITE PROPELLANTS [TERMOELASTER SOM BINDEMEDEL I KOMPOSITKRUT]
M. Ekeberg, B. Stenberg, and R. Sanden Nov. 1994 35 p In SWAHILI Prepared in cooperation with Royal Inst. of Tech.
(PB95-211553; FOA-R-94-00061-2.1-SE) Avail: Issuing Activity (National Technical Information Service (NTIS))

Several commercial thermoplastic elastomers have been studied in order to investigate whether they can be used as a binder for composite propellants. A literature survey is presented and some interesting commercial thermoplastic elastomers of SBS, EVA and polyester type are described. Thermochemical calculations using ammonium perchlorate as an oxidant give a slightly lower impulse than an equivalent HTPB propellant. Without oxidizer, as fuel in air-breathing motors, the two polymers give almost the same impulse. The results suggest that this EVA material is an interesting alternative to HTPB as a binding material in composite propellants. It is also likely to work as a binder for fuel-rich propellants for air-breathing motors such as ducted rocket and solid fuel ramjet engines. NTIS

In this work we study heat and mass transport, fluid motion, and solid/liquid phase change in the process of steady Bridgman growth of Pb(.8)Sn(.2)Te (LTT) in an axially-imposed uniform magnetic field under terrestrial and microgravity conditions. In particular, this research is concerned with the interrelationships among segregation, buoyancy-driven convection, and magnetic damping in the LTT melt. The main objectives are to provide a quantitative understanding of the complex transport phenomena during solidification of the nondilute binary of LTT, to provide estimates of the strength of magnetic field required to achieve the desired

diffusion-dominated growth, and to assess the role of magnetic damping for space and earth based control of the buoyancy-induced convection. The problem was solved by using FIDAP and numerical results for both vertical and horizontal growth configurations with respect to the acceleration of gravity vector are presented. Author

We describe our progress and final conclusions in our theoretical analysis of the growth of thin films of Copper Phthalocyanine (CuPc) via physical vapor transport using a closed cell ampoule. Three projects are discussed. The first is an analysis of the possibility of convection in the ampoule. This provides the most natural explanation for the experimental differences seen in thin films grown on earth and on the Space Shuttle. However we conclude that convection alone is unlikely to be able to explain these differences. The other two projects examined general features of CuPc crystal growth arising from its very anisotropic shape. The second project modeled the CuPc molecule as a hard square shaped object and examined detailed features of the packing of such objects by a physically motivated deposition algorithm. The third project developed a more realistic intermolecular potential for CuPc involving attractive as well as repulsive intermolecular forces. Crystal structures and diffusion barriers were examined. These considerations have more general applicability to the crystal growth of anisotropic molecules on earth, and we believe further work along these lines is called for. DTIC

The Committee on Microgravity Research (CMGR) was made a standing committee of the Space Studies Board (SSB) and charged with developing a long-range research strategy. The scientific disciplines contained within the microgravity program, and covered in this report, include fluid mechanics and transport phenomena, combustion, biological sciences and biotechnology, materials science, and microgravity physics. The purpose of this report is to recommend means to accomplish the goal of advancing science and technology in each of the component disciplines. Microgravity research should be aimed at making significant impacts in each discipline emphasized. The conclusions and recommendations presented in this report fall into five categories: (1) overall goals for the microgravity research program; (2) general priorities among the major scientific disciplines affected by gravity; (3) identification of the more promising experimental challenges and opportunities within each discipline; (4) general scientific recommendations that apply to all microgravity-related disciplines; and (5) recommendations concerning administrative policies and procedures that are essential to the conduct of excellent laboratory science.

METRICS IN METHOD ENGINEERING
S. Brinkkemper and M. Rossi Dec. 1994 29 p
(PB95-197687; Memo-INF-94-79) Copyright Avail: CASI HC A03/MF A01

As customizable computer aided software engineering (CASE) tools, or CASE shells, have been introduced in academia and industry, there has been a growing interest into the systematic construction of methods and their support environments, i.e. method engineering. To aid the method developers and method selectors in their tasks, we propose two sets of metrics, which measure the complexity of diagrammatic specification techniques on the one hand, and of complete systems development methods on the other hand. Proposed metrics provide a relatively fast and simple way to analyze the technique (or method) properties, and when accompanied with other selection criteria, can be used for estimating the cost of learning the technique and the relative complexity of a technique compared to others. To demonstrate the applicability of the proposed metrics, we have applied them to 34 techniques and 15 methods. NTIS

METASCIENTIFIC PROBLEMS IN SAFETY SCIENCE
R. Rosness 31 Dec. 1993 18 p
(PB95-196408; STF75-S93041) Avail: Issuing Activity (National Technical Information Service (NTIS))

This paper is an introduction to a workshop on safety science and the theory of science. The paper examines a study of helicopter safety in order to identify some of the metascientific problems in safety science. It then considers the nature of safety science in more general terms. Finally, it argues that a considerable part of safety science cannot be expected to conform to orthodox falsified criteria of science. This leads to the conclusion that safety scientists should take the responsibility of proposing and justifying norms for empirical and theoretical work in the area. NTIS

SIMPLE MODEL OF FOAM SPREADING ON LIQUID SURFACES
B. Persson and M. Dahlberg 1994 31 p
(PB95-211207; SP-RAPP-94:27) Avail: CASI HC A03/MF A01

An approximate theoretical model of foam spreading on liquids has been formulated. The model is analogous to the spreading of oil slicks on water surfaces. Viscous friction is assumed to be the dominating mechanism in opposing the foam spread. The spreading process is decoupled from the mass transport due to evaporation and drainage of water contained in the foam. The evaporation is assumed to be caused by external radiation, thus simulating the important case of foam spreading on a burning surface. The reduction of the foam layer thickness is accounted for by including a prescribed rate of decrease fixed by the radiation intensity. The decrease rate has been determined in a separate experiment. In the present formulation it is assumed that the foam layer has a triangular shape which presumably is a poor approximation for the initial phase of the spread. More work is needed to find out if this assumption needs to be modified. NTIS

ADVANCED COMPUTATIONAL RESEARCH IN MATERIALS PROCESSING FOR DESIGN AND MANUFACTURING
T. Zacharia 1995 8 p Presented at the 1994 Review of Progress in Quantitative Nondestructive Evaluation Conference, Snowmass, CO, 31 Jul. - 5 Aug. 1994
(Contract DE-AC05-84OR-21400)
(DE95-009130; CONF-9407123-6) Avail: CASI HC A02/MF A01

Advanced mathematical techniques and computer simulation play a major role in providing enhanced understanding of conventional and advanced materials processing operations. Development and application of mathematical models and computer simulation techniques can provide a quantitative understanding of materials processes and will minimize the need for expensive and time consuming trial- and error-based product development. As computer simulations and materials databases grow in complexity, high performance computing and simulation are expected to play a key role in supporting the improvements required in advanced material syntheses and processing by lessening the dependence on expensive prototyping and re-tooling. Many of these numerical models are highly compute-intensive. It is not unusual for an analysis to require several hours of computational time on current supercomputers despite the simplicity of the models being studied. For example, to accurately simulate the heat transfer in a 1-cu m block using a simple computational method requires 10(exp 12) arithmetic operations per second of simulated time. For a computer to do the simulation in real time would require a sustained computation rate 1000 times faster than that achievable by current

supercomputers. Massively parallel computer systems, which combine several thousand processors able to operate concurrently on a problem are expected to provide orders of magnitude increase in performance. This paper briefly describes advanced computational research in materials processing at ORNL. Continued development of computational techniques and algorithms utilizing the massively parallel computers will allow the simulation of conventional and advanced materials processes in sufficient generality. SYSTEM IDENTIFICATION FOR ROBUST PROCESS CONTROL. NOMINAL MODELS AND ERROR BOUNDS Ph.D. Thesis
R. G. Hakvoort 29 Nov. 1994 292 p
(PB95-197026; ISBN-90-370-0114-9) Avail: CASI HC A13/MF A03

The main contribution of this thesis is the development of a robust-control-oriented identification procedure. The identification procedure delivers a nominal model and an explicit model error bound suited for use in high-performance robust process control. The basic steps of the procedure are outlined. After the development of new identification tools, a more detailed description of the entire identification procedure is given in Chapter 8. An essential step in the identification procedure is the identification of a system uncertainty set. This set specifies explicit bounds on the frequency response or weighted pulse response of the system to be identified. The system uncertainty set is constructed on the basis of measurement data and a priori information about the system and the noise which corrupts the data. On the basis of this set both the nominal model and the model error bound are constructed. NTIS

CONSTRUCTION AND PERFORMANCE MEASUREMENT OF A PORTABLE THERMOACOUSTIC REFRIGERATOR DEMONSTRATION APPARATUS M.S. Thesis
Todd J. Berhow Dec. 1994 96 p
(AD-A293265) Avail: CASI HC A05/MF A01

This thesis documents the construction and performance measurement of a portable thermoacoustic refrigerator demonstration apparatus. The objective of the portable refrigerator is to graphically display, as a demonstration during lectures, a substantial thermoacoustic cooling power. Within minutes of start up, the apparatus develops frost on a small metal portion of the device. The refrigerator is small and compact and fits into a portable carrying case along with all ancillary equipment. The construction of the device had been started in a previous thesis project. This thesis describes the remaining construction steps required to complete the refrigerator and the subsequent performance evaluation of the unit in laboratory test trials. DTIC

PREVENTING CRACKING OF ANODIZED COATINGS
Charles C. He (Unisys Corp., Greenbelt, MD.) and Thomas M. Heslin Aug. 1995 13 p
(NASA-TM-104622; Rept-95B00106; NAS 1.15:104622) Avail: CASI HC A03/MF A01

Anodized coatings have been used as optical and thermal surfaces in spacecraft. Particulate contamination from cracked coatings is a concern for many applications. The major cause for the cracking is the difference in the coefficient of thermal expansion between the oxide coatings and the aluminum substrate. The loss of water when the coating is exposed to a vacuum also could induce cracking of the coating. Hot-water sealing was identified as the major cause for the cracking of the coatings because of the large temperature change when the parts were immersed in boiling water and the water was absorbed in the coating. when the hot-water sealing process was eliminated, the cracking resistance of the anodized coatings was greatly improved. Also, it was found that dyed black coatings were more susceptible than clear coatings to cracking during thermo-vacuum cyclings. Author

The end of the Seventies and beginning of the Eighties showed significant technological developments in ballistic missiles, in particular,impact precision. These improvements caused Western strategists to be concerned with use of ballistic missiles equipped with conventional loads against military objectives (the Pact of Varsovie). The concept of ballistic missile tactical had been born. The ballistic vector, which until this time was marked with a 'strategic' label, was then 'standardized' and has interested a number of countries in the process of its development. The world has just entered the era of the ballistic proliferation. From the very start of the Eighties, the United States and, to a lesser degree, NATO lead studies and reflections concerned with defense against tactical ballistic missiles within a East West framework. From these studies the ATBM (Anti Tactical Ballistic Missile) made its appearance. In spite of the attempts at control, missile proliferation has accelerated and led, towards the end of the Eighties and the beginning of the Nineties, to the awakening of a new risk known as proliferating. The 1991 Gulf War was accelerated in this manner. This conflict also clarified the fact that the ballistic weapon constituted a formidable means of pressure for countries which had it, in spite of the PATRIOT, which demonstrated the feasibility of an active defense against ballistic missiles, in spite of their limited performances. This present presentation proposes an overall analysis of the ballistic risk and the possible threat which could result from it and examines the means available for protection against this risk by looking further into all the defensive means. This will constitute the main part of the speech. Lastly, we will endeavor to evaluate the difficulties faced by the architects of the DAMB. CASI

SOSIE: A PRAGMATIC APPROACH TO THE SIMULATION OF BROAD AIR DEFENSE APPLIED TO THE THEATER LEVEL [SOSIE: UNE APPROCHE PRAGMATIQUE DE LA SIMULATION EN DEFENSE AERIENNE ELARGIE APPLIQUEE AU NIVEAU DU THEATRE]
A. Tanter and M. Deas *In* AGARD, Guidance and Control for Future Air-Defence Systems Jan. 1995 8 p In FRENCH (For primary document see N95-32123 11-31)
Copyright Avail: CASI HC A02/MF A03

The SOSIE concept rests on an approach consisting of using existing simulation models of various systems and subsystems and automatically integrating them with minimum modifications within a center of simulation. The defense simulation against ballistic missiles on the theater level calls upon three levels of simulation: DIAMS; TACSIT, and SPOOK. DIAMS presents a fine level system simulation of weapon ground-to-air average carry, TACSIT presents a level of site defense (base air for example), and SPOOK deals with the theater level itself. SOSIE enables users to use the same detailed simulators, developed by an originator of weapon systems or information and communications, without having to know in detail the models of the simulation. Envisioned in the future is the integration of other models of simulations relating to the air-to-air combat, in particular, the networks of command, controls and communications. CASI

TMD DETECTION AND TRACKING USING IMPROVED AWACS SENSORS **c32**
Steve Petersen, Yasuhiro Kinashi (Nichols Research Corp., Vienna, VA.), and Daniel Leslie (Schafer, W. J. Associates, Inc., Arlington, VA.) *In* AGARD, Guidance and Control for Future Air-Defence Systems Jan. 1995 10 p (For primary document see N95-32123 11-31)
Copyright Avail: CASI HC A02/MF A03

This paper identifies an UOES (User Operational Evaluation Systems) version of an airborne surveillance sensor funded by the BMDO (Ballistic Missile Defense Organization). The sensors will be integrated into an operational AWACS E-3 upgrade program. This BMDO program initiative is called Extended Airborne Global Launch Evaluator, or EAGLE. Initial Operational Capability (IOC) of the EAGLE system will be ready in time to support the THAAD/GBR UOES capability. This airborne system, when developed, will consist of a passive infrared surveillance sensor (IRSS) with an active laser-ranger, on board an upgraded AWACS E3 aircraft to operate effectively in the TMD (theater missile defense) mission. The objective for the EAGLE is to field, in a reasonably short time and at a relatively low cost, a cueing sensor capability in regional conflicts to augment the existing space-based surveillance systems. With autonomous surveillance capability to search a wide-sector field, the EAGLE can detect and track boosting TBM's shortly after launch or as they break the clouds. Its passive IR sensor can also detect and track warm hardbody targets. Together with its laser-ranger, it is able to determine, immediately after the booster burn-out, very precise target state vectors that are accurate enough to predict their eventual impact points, to cue fire control radars, and to engage the weapons, if needed. Its primary TMD mission is to provide precise cueing of fire control radars to initiate the active defense weapon systems. Accurate cues from the EAGLE will off load radar resources to enable earlier detection of the targets at longer extended ranges, thereby increasing the interceptor battlespace for potentially more effective defense engagements and opportunities. It can also provide a precise early warning message to enable immediate TBM attack assessment and appropriate selection of defense engagement options by the battle manager. The functions of the sensor suite can be distributed, such that it can be tasked independently to observe the threat intercept, while providing continuous surveillance of new TBM launches, to support the kill assessment function for shoot-look-shoot opportunities. Another potential function that can be performed by the EAGLE is the estimation of TMD launch points (LPE) for counterforce support. This technical paper provides an expanded discussion of the EAGLE's mission roles, specific system functions, and its detection and tracking performance capability. The paper also addresses the sensor and the laser subsystem design characteristics and operational modes required to accomplish all its functions. Initial analyses indicate that the impact of scattering and absorption of the IR signatures and laser signals will be minimal on the performance of the system. Recent satellite data provides measurement of atmospheric extinction. Propagation statistics, based on satellite observations are presented for global regions of interest to TMD. Derived from text

INFRARED AND MILLIMETER WAVE DETECTION USING THIN FILMS OF Pb DOPED BiSrCaCuO SUPERCONDUCTOR **c35**
L. Ngo Phong *In* AGARD, Guidance and Control for Future Air-Defence Systems Jan. 1995 10 p (For primary document see N95-32123 11-31)
Copyright Avail: CASI HC A02/MF A03

Thin film detectors made of CuO superconductors were developed in our laboratory. This article reports details of the fabrication and testing of Pb doped BiSrCaCuO detectors. The detector comprises a film sensor housed in a small cryostat with built-in bias supply and temperature control circuitry. The film sensor was first deposited by magnetron rf sputtering and then crystallized under a rapid thermal annealing process. The characteristics of the response of the detector under millimeter wave and infrared illumination were investigated. The millimeter wave response exhibited a Josephson component with a D(*) approximately 10(exp 8) -

10(exp 9) cm.Hz(exp (1/2))/W in the wavelength range of 3 - 8 mm. The transient response to short pulses indicated a time constant tau less than or equal to 10 ns for this component. The response to laser pulses was thermal in origin and inherently compressible, preventing saturation of the detector electronics to intense beams. The wide band characteristic of the responses at both infrared and millimeter wavelengths could be confirmed. The damage threshold of the film sensor was shown to exceed 10 mJ / sq cm per 3 ns pulse. The possible use of these detectors for threat detection and the optimization of their figure of merit are discussed.

OPTIMAL INFRARED DETECTOR CONFIGURATIONS FOR AIR TARGET DETECTION **c74**

G. Uda and G. Barani *In* AGARD, Guidance and Control for Future Air-Defence Systems Jan. 1995 10 p (For primary document see N95-32123 11-31)

The airtarget detection by a thermal camera is a typical problem of 'hot spot detection' and the knowledge of the available energy on the infrared sensor becomes a critical item to analyse. In order to evaluate the performances of an infrared system in search and track threat warning or passive surveillance, it is necessary to compute the Signal to Noise Ratio (SNR) of the system. The maximization of the SNR is an important goal to assure long detection ranges against stealth threats or cruise missiles with very low emissivities. The large number of detectors is just one of the requirements for this kind of application and some energetic considerations lead up to consider particular geometrical array configurations. Usually, in the SNR evaluation it is assumed that all the energy from a target is focused by the optical system on a single detector element of the array. However, the image of a point source on the focal plane has a finite extent (spot) and its energy distribution is given by the Point Spread Function (PSF) of the optics. The interaction of the finite spot size with the array gives rise to a spreading of the energy impinging on the individual detectors, which causes a decrease of performances. In this paper a statistical evaluation of the loss of energy impinging on the detector due to the finite image size of point targets was performed through a Monte Carlo simulation. By considering the maximum of the energy integrated by a single detector, it is possible to compute the effective SNR of the system. A new figure of merit, called Spreading Factor (SF), defined as the ratio between the maximum of the energy integrated by the single detector of the array and the total energy subtended by the PSF, permits to evaluate the capability of a detector array to detect point sources. Some typical detector and system configurations with their technological impacts have been examined.

The benefits of the ATP (Acquisition Tracking and Pointing) assets to TMD (Theater Missile Defense) are that the platform provides high resolution standoff sensors at low cost and can provide sub micro radian tracking and imaging of dynamic targets, active and passive multispectral data and non-cooperative fire control algorithms. The platform is relatively low cost and can be flown from 4-6 times a year for either sensor performance or phenomenology data collection. The process for collecting and certifying the data are in place and available today. During the past decade we have made significant advances in ATP-FC technologies for ballistic missile defense. The current BMDO ATP assets in general and the HABE testbed in particular can be a key asset in developing TMD weapon systems by providing a means to collect key phenomenology data, test sensor and guidance components, or view and collect data to score test or exercises.

THE HIGH ALTITUDE BALLOON EXPERIMENT DEMONSTRATION OF ACQUISITION, TRACKING, AND POINTING TECHNOLOGIES (HABE-ATP)

D. Dimiduk, M. Caylor, D. Williamson, and L. Larson *In* AGARD, Guidance and Control for Future Air-Defence Systems Jan. 1995 11 p (For primary document see N95-32123 11-31)

The High Altitude Balloon Experiment demonstration of Acquisition, Tracking, and Pointing (HABE-ATP) is a system built around balloon-borne payload which is carried to a nominal 26-km altitude. The goal is laser tracking thrusting theater and strategic missiles, and then pointing a surrogate laser weapon beam, with performance levels end a timeline traceable to operational laser weapon system requirements. This goal leads to an experiment system design which combines hardware from many technology areas: an optical telescope and IR sensors; an advanced angular inertial reference; a flexible multi-level of actuation digital control system; digital tracking processors which incorporate real-time image analysis and a pulsed, diode-pumped solid state tracking laser. The system components have been selected to meet the overall experiment goals of tracking unmodified boosters at 50- 200 km range. The ATP system on HABE must stabilize and control a relative line of sight between the platform and the unmodified target booster to a 1 microrad accuracy. The angular pointing reference system supports both open loop and closed loop track modes; GPS provides absolute position reference. The control system which positions the line of sight for the ATP system must sequence through accepting a state vector handoff, closed-loop passive IR acquisition, passive IR intermediate fine track, active fine track, and then finally aimpoint determination and maintenance modes. Line of sight stabilization to fine accuracy levels is accomplished by actuating wide bandwidth fast steering mirrors (FSM's). These control loops off-load large-amplitude errors to the outer gimbal in order to remain within the limited angular throw of the FSM's. The SWIR acquisition and MWIR intermediate fine track sensors (both PtSi focal planes) image the signature of the rocket plume. After Hard Body Handover (HBHO), active fine tracking is conducted with a visible focal plane viewing the laser-illuminated target rocket body. The track and fire control performance must be developed to the point that an aimpoint can be selected, maintained, and then track performance scored with a low-power 'surrogate' weapon beam. Extensive instrumentation monitors not only the optical sensors and the video data, but all aspects of each of the experiment subsystems such as the control system, the experiment flight vehicle, and the tracker. Because the system is balloon-borne and recoverable, it is expected to fly many times during its development program.

The Mission Management Aid (MMA) program at British Aerospace Defence includes research in the areas of Sensor Data Fusion, Sensor Management, Tactical Situation Assessment and Tactical Decision Aids. Each project has developed and continues to refine workstation prototypes. As the technology in these prototypes matures it is used to update and improve an integrated MMA system prototype. This paper is concerned with the integration process and the issues surrounding it. The factors which influenced progress during integration include the use of compatible development platforms and programming languages for the prototypes, and the choice of a host architecture which allows a flexible approach to the MMA architecture. The benefits gained from the integration framework include the ability to develop integrated displays and controls, to evaluate performance and effectiveness metrics, and to investigate the boundaries and interactions between the subsystems.

Software ROSACE (Optimization of Realistic Systems, Contributes to the Design and the Evaluation), is developed within the framework of the study methodology of multisensors for anti-aircraft defense and is financed by the DRET (contract n 91-34-846). This document concerns a interactive tool, that is evolutionary, portable and of assistance to the definition, the qualification, and the optimization of multisensor systems for anti-aircraft monitoring and defense. This product constitutes a support for the expertise and search for new treatments which utilize the fusion of information and are likely to improve the performance of the system. These algorithms primarily ensure (but not exclusively) the tasks of detection and continuation or classification of air machines and make it possible to analyze the reliability of the system confronted with different scenarios. A prototype Integrated Coastal Surveillance system has been developed on Canada's East Coast to provide effective surveillance out to and beyond the 200 nautical mile Exclusive Economic Zone. The system has been designed to protect Canada's natural resources, and to monitor and control the coastline for smuggling, drug trafficking, and similar illegal activity. This paper describes the Multiple Sensor - Multiple Target data fusion system that has been developed. The fusion processor has been developed around the celebrated Multiple Hypothesis Tracking algorithm which accommodates multiple targets, new targets, false alarms, and missed detections. This processor performs four major functions: plot-to-track association to form individual radar tracks; fusion of radar tracks with secondary sensor reports; track identification and tagging using secondary reports; and track level fusion to form common tracks. Radar data from coherent and non-coherent radars has been used to evaluate the performance of the processor. This paper presents preliminary results. Derived from text

A new approach to multiple target tracking (MTT) problem is developed. The data association (DA) problem is solved by an attributed subgraph isomorphism approach called constellation matching (CM). The CM method exploits, in the most direct way, the spatial configuration of the collection of targets which are subject to temporal and spatial constraints. The CM-based tracking system combines the CM technique with the Kalman filter to track and confirm the trajectories of multiple targets. The efficiency of this new approach is demonstrated using real-life multiple target radar tracking data and the results are compared to those obtained by a multiple hypothesis tracking (MHT) system. The human operator observing the real world is confronted with a huge amount of data from multiple sensor systems observing that world. Multi-sensor data fusion (MSDF) is one of the emerging fields in advanced information processing, concerned with fusing sensor data from these multiple sensor systems. Automated multi-sensor data fusion can help the operator by processing sensor data into concise and surveyable information that is more useful than each sensor system separately can provide. The merit of MSDF can be increased by employing the knowledge of the human operator about the real world, the sensor systems and the fusion process. With the aid of this knowledge, automated MSDF can assign meaning to sensor data and is able to reason about the observed world at a high level, comparable to what humans do. Artificial intelligence provides techniques to represent this knowledge and to reason with it. These techniques are discussed in the context of a generic framework comprising a world model and fusion processes. These techniques can contribute to an effective updating of the world model and can support its fusion processes. In addition, a global distributed fusion architecture based on the framework is proposed. As specific domain of fusion, battlefield surveillance is considered. This paper shows the potential use of artificial intelligence in multi-sensor data fusion. Derived from text

Air forces across the world strive to protect their valuable resources from both the air and ground threats. Over the past few years, the surface-to-air missile threat has become more sophisticated and more deadly. It is far cheaper and less technical for a country to own and operate a ground missile system than to maintain a credible air force. It is for this reason that the attention to the ground threat has grown over the past few years. This paper discusses the approach the U.S. Air Force has taken in protecting its aircraft from these ground threats and how the mission of Lethal Defense Suppression has evolved into the complimentary tasks of Reactive Suppression and Pre-emptive Destruction.

The ability of a defense system to operate effectively when deployed in battle is dependent on designs able to deal with countermeasures against the defense. The formation of a technical Red Team to stress the preliminary

designs of the defensive system with technologically feasible and effective potential countermeasures provides a means to identify such potential countermeasures. This paper describes the experience of the U.S. Ballistic Missile Defense Organization's (BMDO) Theater Missile Defense Red Team since the Gulf War in 1991, the Red-Blue Exchange process, and the value it has provided to the designers of the U.S. Theater Missile Defense systems for developing robust systems. A wide-range of technologically feasible countermeasures has been devised, analyzed, tested for feasibility, and provided to the system developers for mitigation design. The process for independently analyzing possible susceptibilities of preliminary designs and exploiting the susceptibilities to identify possible countermeasures is explained. Designing and characterizing the Red Team's countermeasures, determining their feasibility, and analyzing their potential effectiveness against the defense are explained. A technique for the Blue Team's designers to deal with a wide range of potential countermeasures is explained.

Paint stripping and repainting of aircraft surfaces are required periodically during the operating lifetime of an aircraft. Historically, paint removal has been achieved using chemical strippers, involving materials which contain toxic components and which create hazardous working conditions. The process generates large amounts of hazardous waste from the chemicals used. Alternative methods for aircraft paint removal are now being investigated within the NATO nations with regard to their environmental safety and effective application. These processes include: Plastic Media Blasting, Wheat Starch Dry Media Blasting, Carbon Dioxide Pellet Blasting, Sodium Bicarbonate Blasting and Thermal Decomposition Methods (Laser, Flash Lamps/Carbon Dioxide). The Lecture Series will review these current state-of-the-art alternative methods with environmental effects and related health hazards, costs, process controls, and more. For individual titles, see N95-32166 through N95-32181.

N95-32166# Esquimalt Defence Research Detachment, Victoria (British Columbia).

OVERVIEW OF PAINT REMOVAL METHODS

Terry Foster *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal Apr. 1995 7 p (For primary document see N95-32165 11-31)

Copyright Avail: CASI HC A02/MF A01

With the introduction of strict environmental regulations governing the use and disposal of methylene chloride and phenols, major components of chemical paint strippers, there have been many new environmentally safe and effective methods of paint removal developed. The new methods developed for removing coatings from aircraft and aircraft components include: mechanical methods using abrasive media such as plastic, wheat starch, walnut shells, ice and dry ice, environmentally safe chemical strippers and paint softeners, and optical methods such as lasers and flash lamps. Each method has its advantages and disadvantages, and some have unique applications. For example, mechanical and abrasive methods can damage sensitive surfaces such as composite materials and strict control of blast parameters and conditions are required. Optical methods can be slow, leaving paint residues, and chemical methods may not remove all of the coating or require special coating formulations to be effective. As an introduction to environmentally safe and effective methods of paint removal, this paper is an overview of the various methods available. The purpose of this overview is to introduce the various paint removal methods available. Derived from text

An attempt is made to group the various processes of paint removal into families. The classifications are distinguished by chemical, mechanical, and thermal phenomena. For each of these phenomena, it is possible to identify the main mechanisms brought into play in material removal leading to paint stripping. The chemical strippers used are methylene chloride, phenolic compounds, and activated acids or activated bases free from phenols, chromates or methylene chloride. However, the methylene chloride and phenolic compounds are being replaced by a new generation of chemical strippers which are less active and their solvent power is lower. To improve the chemical kinetics, 'active' elements are introduced into the composition of these products. Mechanical stripping includes technologies using mechanical phenomena based on erosion, achieved by friction or blasting particles. Thermal stripping, the last classification, makes use of electronics and automation. CASI

Chemical strippers based on active phenolic components in a chlorinated solvent have been the traditional method for removing of paints and coatings from aircraft. With the recent recognition of the environmental and health concerns of chlorinated solvents and the problem disposing of phenols there have been some major developments in paint removal technology. One of the first techniques developed to replace chemical strippers and now one of the most widely used techniques for paint removal from aircraft was plastic media blasting (PMB). The PMB technique is similar to traditional grit blasting (slag, sand alumina or carborundum) techniques used on steel and other metals (based on grits) but using polymer based media that are softer and less aggressive. Plastic media are ranked by hardness and density as well as chemical composition. Derived from text

WATER BLASTING PAINT REMOVAL METHODS

Terry Foster *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal Apr. 1995 3 p (For primary document see N95-32165 11-31)

Copyright Avail: CASI HC A01/MF A01

Water blasting is a paint removal technique that has been used for cleaning and paint removal for many years. The major disadvantages until recently were the slow rate of paint removal and the possibility of damage to the substrate from the high pressures used. With the improvement in nozzle design that allows for higher operating pressures and the use of environmentally compliant paint softeners or strippers, water blasting is becoming a recognized technique for paint removal in the aircraft industry. PAINT REMOVAL AND SURFACE CLEANING USING ICE PARTICLES
Terry Foster and S. Visaisouk (Ice Blast International Corp., Victoria, British Columbia.) *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal Apr. 1995 9 p (For primary document see N95-32165 11-31)
Copyright Avail: CASI HC A02/MF A01

Research into the possibility of using ice particles as a blast medium was first initiated at Defence Research Establishment Pacific (DREP) in an effort to develop a more environmentally acceptable paint removal method. A paint removal process was also required that could be used in areas where normal grit blasting could not be used due to the possibility of the residual blasting grit contaminating machinery and other equipment. As a result of this research a commercial ice blasting system was developed by RETECH. This system is now being used to remove paint from substrates that cannot be easily blasted by conventional techniques and also to clean soiled or contaminated surfaces. The problems involved in the development of an ice blast system and its components and their functions are described. Due to the complexity of paint removal using ice blasting, parameters such as air pressure, ice particle size and ice particle flow rate were studied and adjusted to suit the nature of the particular coating and substrate of interest. The mechanism of paint removal by ice particles has also been investigated. A theoretical model has been developed to explain the different paint removal mechanisms such as erosion by abrasion and erosion by fracture as they relate to ice blasting. Finally, the use of ice blasting to removal paint from a variety of substrates is presented as well as examples of surface cleaning and surface decontamination. Author

Mechanical-type stripping using dry ice (solid CO2) consists in blasting particles of dry ice onto the painted surface. This surface can be used alone or in duplex according to type of substrate to be treated. According to operating conditions, three physical mechanisms may be involved when blasting dry ice particles onto a paint system: thermal shock, differential thermal contraction, and mechanical shock. The blast nozzle, nozzle travel speed, blast angle, stripping distance, and compressed air pressure and media flow rate influence the stripping quality and the uniformity and efficiency obtained. Laser beam stripping can be achieved using several active materials: YAG, CO2 Tea, or Excimer. The YAG laser appears to be the most efficient laser assessed in this report. However, the results obtained for productivity, quality, and type of stripping were very poor. Also, for stripping and on account of its specifications, the laser beam can only be used in an automated manner. In spite of these results, it seems that certain companies in Europe have recently developed technical solutions allowing better results to be obtained. Derived from text

At the end of the 80's, some of the large European airlines expressed a wish for paint systems with improved strippability on their aircraft, allowing the possibility to strip down to the primer without altering it, using 'mild' chemical strippers based on methylene chloride. These improvements were initially intended to reduce costs and stripping cycle times while facilitating rapid repainting, and this without the need to change the conventionally used industrial facilities. The level of in-service performance of these paint systems was to be the same as the previous ones. Requirements related to hygiene safety and the environment were added to these initial requirements. To meet customers' expectations, Aerospatiale, within the Airbus Industry GIE, formed a work group. This group was given the task of specifying, following up the elaboration and qualifying the paint systems allowing requirements to be met, in relation with the paint suppliers and the airlines. The analysis made in this report showed the interest of transferring as far upstream as possible (to paint conception level) most of the technical constraints related to stripping. Thus, the concept retained for the paint system, allowing selective chemical stripping, is a 3-coat system with characteristics as near as possible to the previously used paints. Derived from text

The equipment used for plastic media blasting (PMB) is generally independent of the media and is similar to equipment used in traditional abrasive blasting. PMB equipment is usually modified to enable the close control of the media flow and the operation at low pressures (30 - 40 psi). Because of the delicate nature of some of the stripping procedures, the nozzles used for PMB have been redesigned to improve cleaning rates, give an even distribution of particles and reduce the variation in particle velocity across the blast stream. This results in a more equal distribution of particles and impact energies at the substrate. There are three types of blast facilities available: blast cabinets for small components; blast booths which will accommodate larger components but may be used for purposes other than blasting, and blast rooms which are designed for complete vehicles or aircraft and are generally not used for other purposes. TREATMENT OF PLASTIC MEDIA WASTE **c45**
Terry Foster *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal Apr. 1995 1 p (For primary document see N95-32165 11-31)
Copyright Avail: CASI HC A01/MF A01

Although plastic media itself is not generally considered a hazardous waste, the paint particles containing chromate pigments contaminating the spent media are considered a hazardous waste product. There are currently four approaches under investigation aiming to reduce the volume of hazardous waste produced during paint stripping: elimination of the chromate containing pigments or other hazardous pigments from primers and coatings; separation of the paint or hazardous materials from the plastic or other media; encapsulation or recycling of the contaminated media to make it safe for disposal or reuse; and produce a biodegradable media. Research to develop new pigments and primers that will result in the elimination of hazardous pigments such as strontium chromate and in developing alternative anti-corrosive surface treatments to replace cadmium plating is continuing. Contamination of the spent media will remain a problem because the hazardous pigments and surface treatments will still be used on aircraft and their components for the foreseeable future. Therefore, the only realistic alternatives at the moment to reduce the volume of hazardous waste

produced by PMB (plastic media blasting) are to recycle or re-use the media in some form or remove the hazardous materials from the media. Derived from text

The development of a bioremediation process is designed to minimize most of the waste generated with dry media paint removal. The bioremediation method was developed by DOT Technologies in Canada. When paint is removed with wheat starch media, a dust waste is produced containing both starch and paint. The waste will also contain a percentage of inorganic materials from the starch, the paint waste and contaminants from the aircraft (sealants, tapes, ...). This disposal method first uses enzymes to render the starch component soluble in water, converting the starch to various sugars. Specially bred bacteria then digest the sugars, and some of the hydrocarbons in the paint. At this stage, the primary end products are carbon dioxide and water. This bioremediation method reduces the waste generated by dry paint removal by approximately 95 percent. The bacteria, bred by natural selection, tolerates high levels of heavy metals, and toxic hydrocarbons. The basic chemistry of bioremediation, as well as the management of bacteria in this application are summarized hereafter. Derived from text

Although there are six types of plastic media, the focus on operational parameters and materials effects of PMB (plastic media blasting) will be on the Type 5 acrylic media with some reference and comparisons to Type 2 media. The other four plastic media are not used extensively in general aircraft stripping and will not be discussed in this paper. There are several military and commercial documents available with detailed procedures for plastic media stripping of aircraft. The actual choice of blasting parameters will, to a great extent, depend on the media chosen and the substrate to be stripped. The effects of various blasting conditions on materials can be evaluated using visual, optical microscopy, scanning electron microscopy (SEM) and mechanical and corrosion test methods. In some test methods up to twelve specimens are required to give meaningful results, therefore statistical analysis tools are also required to interpret the results due to the scatter in some of the data. It is not always easy to conduct a study and implement a systematic policy in the aeronautical paint stripping field. The situations to be studied are complicated by extensive technical data, material conditions and financial unknowns. To these are added demands both in the civil and military fields to increase the performance obtained, optimize cycles, reduce recurrent costs, quickly amortize investments and now increasing respect for the environment. To reply correctly, the various possibilities must be assessed using, if possible, identical criteria and reference systems. The only criterion which applies to all the processes and methods is the overall stripping cost. It is not sufficient for a process to meet the related technical requirements (for example 'IATA guidelines'), it must also be economically justifiable. The overall costs take into account therefore the costs and materials, labor and also the downtime of the aircraft, amortization and maintenance of the installations and processing of waste, etc. For many years now, AEROSPATIALE has undertaken research and development programs to find and evaluate alternatives to the conventional chemical stripping process. This work has led it to carry out comparative analyses from technical elements enhanced as the work progressed. Derived from text

STANDARDIZATION WORK
Olivier Malavallon *In* AGARD, Environmentally Safe and Effective Processes for Paint Removal Apr. 1995 1 p (For primary document see N95-32165 11-31)
Copyright Avail: CASI HC A01/MF A01

For several years now, the main civil aircraft manufacturers (Airbus and its partners, Boeing, Fokker, McDonnell Douglas) have been working jointly on the writing of technical recommendations and the drawing up of an international standard. This work concerns the evaluation of the processes and products used to strip aeronautical paint systems. This procedure was initiated on request from the main airlines. In effect, the airlines are faced with situations in which the financial and operational objectives are becoming increasingly important. The need was felt to rationalize and, if possible, harmonize the criteria and technical requirements of the various civil aircraft manufacturers in order to facilitate in-service maintenance of the fleets of airlines operating Airbus, Boeing, Douglas aircraft, etc. Derived from text

THE INTERACTION OF MAGNETIZATIONS WITH AN EXTERNAL ELECTROMAGNETIC FIELD AND A TIME-DEPENDENT MAGNETIC AHARONOV-BOHM EFFECT
G. N. Afanasev, M. Nelhiebel (Technische Univ., Vienna, Austria.), and Yu. P. Stepanovskij (Academy of Sciences of the Ukraine, Kharkov, Ukraine.) 1994 20 p
(DE95-613463; JINR-E-2-94-297) Avail: CASI HC A03/MF A01 (US Sales Only)

We investigate how the choice of the magnetization distribution inside the sample affects its interaction with the external electromagnetic field. The strong selectivity to the time dependence of the external electromagnetic field arises for the particular magnetizations. This can be used for the storage and ciphering of information. We propose a time-dependent Aharonov-Bohm-like experiment in which the phase of the wave function is changed by the time-dependent vector magnetic potential. The arising time-dependent interference picture may be viewed as a new channel for the information transfer. DOE

(AD-A291491; AF95-1) Avail: CASI HC A05/MF A01

Circuit boards are used in nearly every electrical appliance. Most

board failures cause differing currents in the circuit board traces and components. This causes the circuit board to radiate a differing electromagnetic field. Imaging this radiated field, which is equivalent to measuring the field, could be used for error detection. Using estimates of the fields radiated by a low power digital circuit board, properties of known materials, and available equipment, we determined how well the following technologies could be used to visualize circuit board electromagnetic fields (prioritized by promise): electrooptical techniques, magnetooptical techniques, piezoelectric techniques, thermal techniques, and electrodynamic force technique. We have determined that sensors using the electrooptical effect (Pockels effect) appear to be sufficiently sensitive for use in a circuit board imaging system. Sensors utilizing the magnetooptical effect may also be adequate for this purpose, when using research materials. These sensors appear to be capable of achieving direct broadband measurements. We also reviewed existing electromagnetic field sensors. Only one of the sensors (recently patented) was specifically designed for circuit board measurements. DTIC

MICROWAVE REPEATER WITH BROADBAND ACTIVE AND/OR PASSIVE ISOLATION CONTROL Patent
Emanuel Briguglio, inventor (to Navy) 13 Dec. 1994 6 p Filed 31 Dec. 1990
(AD-D017358; US-Patent-5,373,297; US-Patent-Appl-SN-638114; US-Patent-Class-342-15) Avail: US Patent and Trademark Office

A microwave repeater with antenna isolation comprises a first receiving antenna for receiving an input signal from a distant source; an amplifier section for amplifying and modulating the input signal to produce an output signal; a transmitting antenna coupled to the amplifier section; and an isolation control means including a second receiving antenna for isolating the first receiving antenna from the transmitting antenna. In one preferred embodiment, the second receiving antenna is aligned so as to match the gain and phase from the transmitting antenna to the first receiving antenna. The isolation control means comprises a phase shifter coupled to the second receiving antenna; and a power combiner having inputs coupled to the first receiving antenna and the phase shifter and an output coupled to the amplifier section. The power combiner receives the input signal from the first receiving antenna and a 1 SO phased shifted signal from the phase shifter. DTIC

INTERFERENCE REJECTION TECHNIQUES IN A DS SPREAD-SPECTRUM HF RADIO SYSTEM [INTERFERENSUNDERTRYCKNING I ETT DS-RADIOSYSTEM FOER KORTVAGSKOMMUNIKATION]
N. Hallqwist and B. Lagerquist Dec. 1994 63 p In SWAHILI
(PB95-211660; FOA-R-94-00066-3.5-SE) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report presents results from research and simulations of different algorithms for interference rejection in a direct-sequence spread-spectrum high frequency (HF) radio system. The overall purpose of the efforts was to propose a practical working method and to investigate possible gains, using the BER (bit error rate) as performance measure. The simulations have been performed using the simulation program SPW. The interference environment is assumed to consist of white Gaussian noise, and/or narrowband interfering signals, distributed according to the Laycock-Gott model. The proposed algorithm transforms the signals, excludes the largest 10 percent of the components and finally performs an inverse transform. The results predict that considerable gains can be expected using this interference rejection method. NTIS

UNCONVENTIONAL IMAGING FIELD EXPERIMENT PLAN Final Report, Jun. 1993 - May 1994
James R. Fienup, Jack N. Cederquist, Joseph C. Marron, and Richard G. Paxman Dec. 1994 145 p
(Contract N00014-93-C-0093)
(AD-A291492; Rept-253200-7-F) Avail: CASI HC A07/MF A02

We investigated the feasibility of conducting experiments at the Innovative Science and Technology Experimental Facility (ISTEF). The experiments are to test unconventional imaging concepts that use laser illumination and pupil-plane detection. We show the trade-off between the sparsity of the number of sub-apertures and the number of speckle realizations collected. We invented and demonstrated two new algorithms for phasing heterodyne arrays that work for sparse arrays of detectors. We performed analysis showing that near-ground turbulence makes the isoplanatic patch size for a 10 km horizontal path impractically small, but for a 1 km path it can be accommodated by using a small target. We invented a new imaging modality involving collection of intensity data at multiple wavelengths from which we can reconstruct a 3-D image using an opacity constraint. We invented a new sparse-array pattern design in the shape of an arrow that fills a square OTF with a smaller number of sub-aperture than computer-optimized patterns. We showed that we can trade off background suppression for the ability to measure multiple speckles over a sub-aperture by placing the detector array in a plane beyond the focal plane. DTIC

SIX-VECTOR FORMALISM IN ELECTROMAGNETICS OF BIANISOTROPIC MEDIA
I. V. Lindell, K. Sihvola, and K. Suchy Jul. 1994 16 p
(PB95-207130; ISBN-951-22-2218-3) Avail: CASI HC A03/MF A01

Notation applying six-vectors and six-dyadics appears very applicable for describing electromagnetic problems in general bianisotropic media because, with normal three-vector notation, the analytic expressions often tend to be very complicated. Power of the notation is increased by introducing some operations with which recourse to the three-vector and three-dyadic notation during the analysis can be avoided. A number of theorems and concepts of electromagnetic fields in bianisotropic media are given as examples of applying the six-vector and six-dyadic notation. NTIS

SIGNAL-PROCESSING THEORY FOR THE TurboRogue RECEIVER
J. B. Thomas 1 Apr. 1995 97 p
(Contract NAS7-1260)
(NASA-CR-198882; JPL-Publ-95-06; NAS 1.26:198882) Avail: CASI HC A05/MF A02

Signal-processing theory for the TurboRogue receiver is presented. The signal form is traced from its formation at the GPS satellite, to the receiver antenna, and then through the various stages of the receiver, including extraction of phase and delay. The analysis treats the effects of ionosphere, troposphere, signal quantization, receiver components, and system noise, covering processing in both the 'code mode' when the P code is not encrypted and in the 'P-codeless mode' when the P code is encrypted. As a possible future improvement to the current analog front end, an example of a highly digital front end is analyzed. Author

MICROWAVE COUPLING INTO A SLOTTED CAVITY. ADDITIONAL RESULTS
M. Baeckstroem and J. Loren Dec. 1994 56 p
(PB95-210381; FOA-R-94-00042-3.2-SE) Avail: CASI HC A04/MF A01

Further evaluation of simple formulas for shielding effectiveness and for absorption cross section of a wire inside a shielded structure have been made. The results give further support to the expressions, derived earlier in FOA report C 30712-8.3,3.2 (PB94-123742). The main objective of the work has been to find and evaluate simple expressions for microwave coupling into electronic compartments. The expressions are intended to be used for bounding calculations in design and analysis of system hardness against intense microwave radiation, e.g. HPM (High Power Microwaves). It is shown that introduction of microwave absorbing material into the cavity gives an expected increase in shielding effectiveness. It is also shown that shielding effectiveness depends only to a little extent on the position and length of the wire. The total transmission area for multiple apertures can be expressed as the sum of the areas of the individual apertures. The absorption cross section for a wire inside the cavity is shown to depend only slightly on wire position and length, even when the wire is located very close to a wall. The results lead to further improvement of the methodology for analysis of system hardness against HPM radiation. It also lays a foundation for a more scientific approach in the design of shielded structures. Such an approach would result in an increased reliability and also in a reduction of costs due to a reduced need for (large) safety margins and fewer late design modifications. The report also proposes a new method to measure shielding effectiveness of apertures. NTIS

WAVEFRONT SIMULATOR FOR EVALUATING RF COMMUNICATION ARRAY SIGNAL PROCESSORS Patent
Steven B. Minarik, inventor (to Navy) 16 Aug. 1994 15 p Filed 27 Oct. 1993
(AD-D017372; US-Patent-5,339,087; US-Patent-Appl-SN-145352; US-Patent-Class-342-375) Avail: US Patent and Trademark Office

A wavefront simulator that emulates plane wave propagation from multiple transmitting antennas is used to evaluate, in both a static and a dynamic manner, an array processor used in RF communications to determine the location of transmitting antennas and possibly to perform beamforming for cancelling the energy of an interfering transmitter. The wavefront simulator generates time delay signals, giving the appearance of being emitted from different transmitters or sources, and simulates those signals as being received by an antenna array associated with the array processor. The array processor utilizes the time delay signals to calculate, e.g., the angle of arrival of the signals from the emitting antennas. DTIC

SCATTERING AND RADIATION FROM CYLINDRICALLY CONFORMAL ANTENNAS Ph.D. Thesis
Leo Charles Kempel 1994 180 p
Avail: Univ. Microfilms Order No. DA9423227

Microstrip patch antennas offer considerable advantages in terms of weight, aerodynamic drag, cost, flexibility, and observability over more conventional protruding antennas. Two hybrid finite element methods are presented and are used to examine the scattering and radiation behavior of cylindrically conformal patches. In conjunction with a new divergence-free cylindrical shell element, the finite element-boundary integral method is shown to have low computational and memory requirements when compared with competing approaches. This method uses an efficient creeping wave series for the computation of the dyadic Green's function and a uniform surface mesh so that a fast Fourier transform may be used to reduce the computational and memory burden of the method. An alternative finite element-absorbing boundary condition approach incorporates a new conformal vector condition which minimizes the computational domain. The latter method is more flexible than the former because it can incorporate surface coatings and protruding antennas. Guidelines are established for minimal ABC displacement from the aperture. These two hybrid finite element methods are used to study the scattering, radiation, and input impedance of typical conformal antenna arrays. In particular, the effect of curvature and cavity size is examined for both discrete and wraparound antenna arrays. Dissert. Abstr.

APPARATUS AND METHOD FOR PRODUCING THREE-DIMENSIONAL IMAGES Patent
Kenneth K. Knaell, inventor (to Navy) and Glen R. Heidbreder, inventor (to Navy) 28 Feb. 1995 13 p Filed 30 Sep. 1993
(AD-D017455; US-Patent-5,394,151; US-Patent-Appl-SN-129499; US-Patent-Class-342-25) Avail: US Patent and Trademark Office

An apparatus and method is capable of acquiring useful three-dimensional radar images from an aircraft which travels in a curvilinear path to generate only a sparsely filled synthetic array. A motion measurement unit outputs position measurements as the aircraft travels in the curvilinear path. The system includes a motion compensation and timing unit and a wave transmitter which outputs chirped radar signals. An antenna coupled to the wave generator sends the chirped radar signals to a region to be imaged and receives scattered chirped radar return signals from scatterers in the region. DTIC

DYNAMIC ROUTATION IN DISTRIBUTED ENVIRONMENTS
L. J. N. Franken, P. Janssen, B. R. Haverkort, and G. vanLiempd 7 Sep. 1994 36 p Prepared in cooperation with PTT Research
(PB95-197968; Memo-INF-94-62) Copyright Avail: CASI HC A03/MF A01

In this paper, we address the issues of communication routing and process allocation in an integrated way, the so-called routations. After the definition of a formal framework for distributed systems and their applications, routations can be defined. Existing routing and allocation algorithms are discussed in a unified way, using this framework. This facilitates the basis for a proper comparison of algorithms. We then propose a routation algorithm based on the A* intelligent tree-search algorithm. Although this algorithm yields optimal routations, it is too slow to be used in practice. We therefore developed three heuristics, each again in three variants, that accomplish the same task, however, with far reduced computational effort. We then propose to use the A* algorithm in combination with one of the heuristics in a real distributed environment. In the appendices we describe the pseudo-codes of the introduced algorithms, as well as an experimental, ANSAware-based, distributed system in which the routations take place using the heuristics we developed. PROPAGATION AND SCATTERING OF ELASTIC WAVES IN LAMINATED CIRCULAR CYLINDERS Ph.D. Thesis
Nipon Rattanawangcharoen 1993 134 p
(ISBN-0-315-85957-1) Avail: Univ. Microfilms Order No. DANN85957

Propagation and scattering of guided elastic waves in circular cylinders are investigated. An analytical method is formulated to study wave propagation in laminated isotropic cylinders while Rayleigh-Ritz type approximations are developed for laminated composite cylinder where the analytical solutions are unattainable. The effects of circumferential wavenumber, thickness to radius ratio, ply lay-up configuration, and layering on dispersion characteristics of free guided waves are investigated through these techniques. The problem of reflection of waves normally incident upon the free end of cylinders is studied as a special case of wave scattering problems. A wave functions expansion procedure is employed in developing least square and variational methods for the investigation. Numerical results demonstrate the successful application of the Rayleigh Ritz type approximation and the variational technique for the free end reflection problem in laminated composite cylinders. A hybrid method is presented to analyze the scattering of plan strain waves by load or flaw in cylindrical cross-section. The domain of the cross-section is divided into two regions, an interior region and an exterior region. The interior region which contains the load or flaw is modeled by finite elements while a wave functions expansion is employed for the exterior region. The numerical results for the scattered amplitudes from the load and from flaw are presented for Zr-Nb pressure tube. Dissert. Abstr.

The purpose of this phase of the project was to develop fast algorithms for computations of electromagnetic scattering (radar), and assist in the implementation and development of fast engineering software using these algorithms by the team at Hughes Research Laboratories. Present methods for computing radar cross sections and other scattering crossections are severely limited by prohibitive processing and memory requirements. New fundamental Fast Multipole Methods developed over the last few years by Rokhlin (for 2-D scattering) held the promise for breaking this computational bottleneck, the goal set out in this project was to extend the work to higher dimensions and to complete the computational infrastructure needed for converting these algorithms to engineering tools. The codes and algorithms obtained in this joint effort between HRL and FMAH have already changed the state of the art in this area of electromagnetics simulations and promise to revolutionize computational design technology. We have verified that these algorithms provide the expected improvements and scaling. DTIC

ADVANCED SIGNAL PROCESSING FILTER Patent Application
Ronald A. Wagstaff, inventor (to Navy) 30 Sep. 1994 22 p
(AD-D017324; US-Patent-Appl-SN-314281) Avail: CASI HC A03/MF A01

A filter, and method of the filtering, for increasing the signal to noise ratio of relatively small and constant amplitude signals in the presence of relatively large and varying amplitude signals. The filter produces a filtered power level az proportional to az = (Sum of xi(-z) from i = 1 to N)(-1/z) where x1 are power realizations of the signal in a selected frequency bin, and i = 1, 2, . . ., N, and z is a non-zero real number not equal to -1, 0, or 1, and is preferably positive. For positive z, because filtered power level a2 depends on a sum of xi(-z), sum az disproportionately favors smaller, more stable, signals. DTIC

A method for determining the frequency of a real sinusoid is proposed. Based on exponential sampling of the waveform, the approach requires virtually no computation. It can be easily implemented in digital hardware. A dynamic programming algorithm and a suboptical kit computationally efficient method for estimation of a chaotic signal in white Gaussian noise are proposed. The nonlinear map is assumed known so that only the initial condition need be estimated. Computer simulations confirm that both approaches produces efficient estimates at high signal-to-noise ratios. DEVELOPMENT OF A NOVEL WIND LIDAR, PHASE 1 Final Report, 13 May - 13 Nov. 1994
H. S. Lee 8 Feb. 1995 35 p
(Contract F49620-94-C-0052)
(AD-A292703; AF-94-1; AFOSR-95-0177TR) Avail: CASI HC A03/MF A01

A prototype new incoherent Doppler lidar system was designed for atmospheric wind measurements with a high accuracy up to a 5 kilometer slant path range in Phase 1. This sensor is based on the pseudo-random modulation CW lidar technique in conjunction with a new incoherent Doppler lidar method, in which the return PRM laser signal is passed through a Doppler filter before being digitally processed to determine range resolved wind velocity in real time. Extensive simulation study shows, in the baseline system configuration with a 50 cm receiver and one watt transmitter power, a 200 seconds signal integration will provide the required signal to noise ratio for a few percent accuracy measurement which corresponds to 1 m/s accuracy over a 50 m/sec dynamic range. Our Phase 1 experiment provided a unique technology basis for the construction of a high power narrow linewidth SLM diode laser system for cost effective and robust PRM laser transmitter. Consisting of the transmitter module, solid etalon based Doppler filter module, PRM data module and a receiver module, the sensor will be compact and lightweight with low power consumption and low cost. The sensor will be intrinsically insensitive to noise, background radiation, and other system bias. DTIC

ANALOG PREPROCESSING IN A SNS 2 MICROMETERS LOW-NOISE CMOS FOLDING ADC M.S. Thesis
Richard D. Carr Dec. 1994 120 p
(AD-A293356) Avail: CASI HC A06/MF A02

Significant research in high performance analog-to-digital converters (ADC's) has been directed at retaining part of the high-speed flash ADC architecture, while reducing the total number of comparators in the circuit. The symmetrical number system (SNS) can be used to preprocess the analog input signal, reducing the number of comparators and thus reducing the chip area and power consumption of the ADC. This thesis examines a Very Large Scale Integrated (VLSI) design for a folding circuit for a SNS analog preprocessing architecture in a 9-bit folding ADC with a total of 23 comparators. The analog folding circuit layout uses the Orbit 2 micrometers CMOS N-well double-metal, double-poly low-noise analog process. The effects of Spice level 2 parameter tolerances during fabrication on the operation of the folding circuit are investigated numerically. The frequency response of the circuit is also quantified. An Application Specific Integrated Circuit (ASIC) is designed. DTIC

INVERSE AND CONTROL PROBLEMS IN ELECTROMAGNETICS Final Report, 1 Jul. 1991 - 30 Jun. 1994
T. S. Angell and R. E. Kleinman 30 Jun. 1994 236 p Limited Reproducibility: More than 20% of this document may be affected by poor print
(Grant AF-AFOSR-0277-91)
(AD-A292993; AFOSR-95-0199TR) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This report summarizes work carried out in a number of specific areas of investigation in inverse scattering and optimal control problems in electromagnetics. The progress is briefly described and detailed results are included in an appendix. The major accomplishments include: the application of multi-criteria optimization techniques to problems in antenna design; the development of inverse scattering algorithms which use scattered field data in the frequency domain to reconstruct the well posedness of electromagnetic scattering problems with resistive or conductive boundary conditions; and derivation of new boundary integral equations for electromagnetic scattering from local distributions of a plane screen. In addition some new results on low frequency scattering have been found which establish the exact nature of the asymptotic expansion in two dimensions. DTIC

The work summarized in this report covers research carried out at Cornell University during the period 2/01/93 to 10/31/94. During this period our research focused on the generation of ultra high power microwave signals, especially on the elimination of sidebands from the amplifiers used, and in the latter period on the possibility of developing a tuneable high power amplifier. In this report we summarize both aspects of our program. Details of the results obtained may be found in the published papers, copies of which are appended to this report. DTIC

PLANE WAVE REFLECTION FROM A UNIAXIAL CHIRAL QUARTER-WAVE POLARIZATION TRANSFORMER
A. J. Viitanen Jun. 1994 14 p
(PB95-206512; ISBN-951-22-2210-8) Avail: CASI HC A03/MF A01

A uniaxial chiral slab is shown to have applications as a polarization transformer by choosing the thickness of the slab and the material parameters properly. The slab transforms linear polarization to any elliptic polarization by rotating the slab. The reflection coefficients for the slab are calculated numerically and the results show us that by choosing the material parameters properly the reflection from the slab can be minimized. This is very important for practical applications of the chiral quarter-wave polarization transformer. NTIS

AUTOMATION OF THE CONTROL OF ACOUSTIC PARAMETERS IN A DIGITAL SPEECH SYNTHESIZER [AUTOMATYZACJA STEROWANIA PARAMETRAMI AKUSTYCZNYMI W CYFROWYM SYNTEZATORZE MOWY]

Ignacy Nowak, Mariusz Owsianny, and Janusz Imoilczyk Feb. 1995 31 p In POLISH
(ISSN 0208-5658)
(IFTR-2/1995) Avail: CASI HC A03/MF A01

The authors describe the results of their modifications of the implementation of a formant model for a serial-parallel speech synthesizer which operates according to D. H. Klatt's system. The basic version of the implementation was developed at the Acoustic Phonetics Workshop of the Institute of Basic Problems of Technology of the Polish Academy of Sciences in Poznan by M. Owsianny. The modifications proceeded in several directions, including: (1) adaptation of the control of the model to synthesize complex sequences of Polish vowels; (2) improvements in the speed of the programmed synthesis model; and (3) modification of the user interface for the software. The accomplishment of the most important part of the work (item 1 above) made it possible to: (1) switch between different synthesis modes without conflict (within a single synthetic utterance); (2) simplify the synthesis mode switching system; and (3) provide precise control of parameters in extending the synthesis process to subsequent time frames. All of these improvements made it possible to speed up the synthesis process without adversely affecting the quality of the synthesized speech and make the synthesizer software much more comfortable for users. The new synthesizer software requires better hardware than the old software, with the minimum requirements being an IBM PC 386 with a math co-processor. Author

HIGH FREQUENCY (HF) UPGRADE STUDY FOR THE CANADIAN REGIONAL OPERATIONS CONTROL CENTER (ROCC) AWACS DIGITAL INFORMATION LINK (RADIL) PROJECT Final Report

Kenneth Wickwire Apr. 1995 78 p
(Contract F19628-89-C-0001)
(AD-A293435; MTR-93B0000141; ESC-TR-95-104) Avail: CASI HC A05/MF A01

The Regional Operations Control Center AWACS Digital Information Link/Rapidly Deployable Integrated Command and Control System (RADIL/RADIC) System Program Office, Canadian RADIL Program, has acquired high-frequency (HF) radio equipment for two Canadian ground stations under the RADIL Project. This equipment will allow those stations to carry out Tactical Digital Information Link (TADIL) A data transmissions assisted by MIL-STD-188-141A automatic link establishment (ALE). The MITRE Corporation has been tasked to study whether U.S. TADIL stations should be equipped with similar HF-ALE modems. This report analyzes the improvements in performance over northern links that can be expected from the addition of ALE to the TADIL A system. Since there is only a small amount of data on ALE-assisted digital communications in northern regions, the analysis combines a probabilistic approach to comparison of ALE and conventional linking techniques with actual HF propagation data from links in Canada, Iceland, and Norway. The report also assesses the risks to effective communications of using an ALE-TADIL A system in the north and recommends several improvements in hardware and software that can lower those risks. DETECTION OF RADAR TARGETS USING HIGHER-ORDER STATISTICS Patent

Robert D. Pierce, inventor (to Navy) 28 Mar. 1995 18 p Filed 28 Sep. 1993
(AD-D017442; US-Patent-5,402,131; US-Patent-Appl-SN-127619; US-Patent-Class-342-194) Avail: US Patent and Trademark Office

A signal detection system, preferably for use with a coherent radar system selects certain combination of input signal samples in a block of signal samples to derive a test statistic which is unbiased by Gaussian noise. Products of pairs of sample values are stored in a data sample look-up table. An index look-up table is created by scanning through possible combinations of addresses and excluding those combinations of sample values which would be redundant over other combination and would result in a contribution to biasing by noise. MULTI-DIMENSIONAL DATA COMPRESSION FOR PORTABLE COMMUNICATION Final Report, 1 Aug. 1991 - 31 Dec. 1994

Teresa H. Meng 1995 44 p
(Contract DABT63-91-K-0002)
(AD-A292751) Avail: CASI HC A03/MF A01

This project provides an integrated design approach of a portable video on demand system capable of delivering high quality image and video in a wireless communication environment. The research focuses on both the algorithm and circuit design techniques developed for implementing a low power video compression/decompression system at power levels that are two orders of magnitude below existing solutions. The three main technological challenges in realizing such a system are high compression efficiency for transmission bandwidth reduction, error resiliency to minimize the effects of channel error, and low power implementation for portability. This final report summarizes research accomplishments supported by AFOSR Grant F49620-92-J-0002. Over the three-year period of support under this grant we have had considerable success in each of the several components of our research program, namely the development of multiresolution statistical approaches to problems of image analysis, the analysis of singular systems with applications in efficient processing of multidimensional data, large-scale estimation and computation in remote sensing and space-time data assimilation, multiresolution and wavelet-based methods for the detection and classification of abrupt changes in signals, and data fusion and inversion using multiresolution and wavelet-based methods. In this report we outline our accomplishments in each of these areas and also include a complete list of reports and publications describing this work. DTIC

This report documents the design and development of a prototype information communications system for quad-service use in a theater of operations. The prototype was designed to allow seamless integration of legacy information systems operated by each of the four services, and is based on a combination of software interfaces and commercial satellite communications hardware. The QSTARS-MS prototype has been tested in a variety of garrison and deployment settings including extensive use in Somalia and the former Yugoslav republics. The prototype demonstrates the feasibility of achieving joint interoperability through rapidly designed interfaces between legacy information systems. The prototype also offers world-wide, portable, and affordable satellite communications capability through the use of the International Maritime Satellite network. DTIC

INVESTIGATION OF MICROWAVE BACKSCATTER FROM THE AIR-SEA INTERFACE Final Report
Robert E. McIntosh and James R. Carswell [1995] 22 p
(Grant NAGw-1112)
(NASA-CR-198854; NAS 1.26:198854) Avail: CASI HC A03/MF A01

Monitoring the ocean surface winds and mean ocean surface level is essential for improving our knowledge of the climate. Two instruments that may provide us with this information are satellite-based scatterometers and altimeters. However, these instruments measure the backscatter characteristics of the ocean surface from which other physical parameters, such as the wind speed or ocean surface height, are derived. To improve the algorithms or models that relate the electromagnetic backscatter to the desired physical parameters, the University of Massachusetts (UMass) Microwave Remote Sensing Laboratory (MIRSL) designed and fabricated three airborne scatterometers: a C-band scatterometer (CSCAT), Ku-band scatterometer (KUSCAT) and C/Ku-band scatterometer (EMBR). One or more of these instruments participated in the Electromagnetic Bias experiment (EM Bias), Shelf Edge Exchange Processes experiment (SEEP), Surface Wave Dynamics Experiment (SWADE), Southern Ocean Wave Experiment (SOWEX), Hurricane Tina research flights, Tropical Ocean Global Atmosphere Coupled Ocean-Atmosphere Response Experiment (TOGA COARE), and Ladir In-space Technology Experiment (LITE). This document describes the three scatterometers, summarizes our measurement campaigns and major contributions to the scientific and engineering communities, lists the publications that resulted, and presents the degrees earned under the support of this NASA grant. FUNCTIONS FOR PROCESSING SYNTHETIC APERTURE RADAR IMAGERY
Robert Whatmough and Paul Whitbread Jan. 1995 47 p
(AD-A293895; DSTO-TR-0146; DODA-AR-008-799) Avail: CASI HC A03/MF A01

The INGARA synthetic aperture radar system can potentially benefit from higher level algorithms and software to enhance its basic imagery so that important features are obvious to human operators. These could include filters for removing speckle, zooming functions for correcting the aspect ratio of the imagery and classifiers for distinguishing ground cover types. The system could also make use of a development environment in which such functions can be easily developed and trialled. This Note describes the Khoros image processing system and functions added to that system by researchers in ITD that could be of use in processing INGARA data. It also includes results of tests of the effectiveness of these functions in enhancing sample INGARA data. DTIC

INVESTIGATION OF GROUND TARGET DETECTION METHODS IN FULLY POLARIMETRIC WIDE ANGLE SYNTHETIC APERTURE RADAR IMAGES M.S. Thesis
Wayne B. Laggan Mar. 1995 177 p
(AD-A293922; AFIT/GE/ENG/95M-02) Avail: CASI HC A09/MF A02

Target detection is a high priority of the Air Force for the purpose of reconnaissance and bombardment. This research investigates and develops methods to distinguish ground targets from clutter (i.e. foliage, landscape etc.) in Wide Angle Synthetic Aperture Radar (WASAR) images. WASAR uses multiple aspect angle SAR images of the same target scene. The WASAR data was generated from a pre-release software package (XPATCH-ES) provided by the sponsor (WL-AARA). A statistical analysis and feature extraction is performed on the XPATCH-ES data. Polarimetric and wide angle covariance matrices are estimated and analyzed. From an analysis of the wide angle covariance matrix it is shown that natural clutter has in general a uniform radar return for changing aspect angles, whereas the radar return for a target varies. Based on this analysis, two new wide angle algorithms, the WASAR Whitening Filter and the Adaptive WASAR Whitening Filter (AWWF) are developed. The target detection performance of polarimetric and multi aspect angle image combining algorithms are quantified using Receiver Operating Characteristic curves and target to clutter ratios. It is shown that wide angle processing provides superior target detection performance over polarimetric processing. Combinations of wide angle and polarimetric algorithms were used to achieve a 13.7 dB processing gain in target to clutter ratio when compared to unprocessed images of the target scene. This represents a significant improvement in target detection capabilities. DTIC

RESEARCH IN GROUND-TO-AIR MICROWAVE IMAGING Final Report
Bernard D. Steinberg and Donald Carlson Mar. 1995 29 p
(Contract DAAL03-89-K-0066)
(AD-A292907; UP-VFRC-11-95; ARO-25350.15-EL) Avail: CASI HC A03/MF A01

Many potential applications exist for high resolution radar such as direction finding, high accuracy tracking, target counting, and high resolution radar imaging. All of these applications require the use of large, thinned, random or periodic antenna arrays. Many uncertainties exist in such large antenna systems. For example, exact element positions are generally not known because of surveying problems or flexing of the large antenna structure. Adaptive beamforming (ABF) is the solution to the unusual design that achieves these objectives. It deduces the errors in the locations of the receivers that are distributed around the airport or on the air frame and automatically compensates for them in the image processing. This year's work concentrated on three tasks. The first was to develop a generalized ABF theory for the class of spatial correlation algorithms. The second was to extend the resolution of a microwave imaging radar to 15 cm, and the third was to study enhanced target detection sensitivity and target recognition. DTIC

DYNAMIC MAINTENANCE SCHEDULING FOR A STOCHASTIC TELECOMMUNICATION NETWORK: DETERMINATION OF PERFORMANCE FACTORS
Todd S. Patterson Mar. 1995 133 p
(AD-A293829; AFIT/GOR/ENS/95M-14) Avail: CASI HC A07/MF A02

This research proposes an analytical approach to access the relationship between maintenance facility location and communication network performance measurement using a selected dynamic maintenance scheduling protocol. There were three objectives established for this effort. The first objective was the determination of an upper-bound upon the level of performance for a telecommunication network using dynamically scheduled maintenance to evaluate maintenance depot location. This was achieved by using a two-stage algorithm, first locate a maintenance depot by using stochastic algorithms, and then to measure the resulting impact upon performance with a multi-commodity network flow model. The second objective was to develop the metrics by which network performance should be measured. This was accomplished by comparing multiple criteria using a constraint conversion technique. The third objective created the mathematical models necessary to evaluate network operations. The models were created within a least-cost multi-commodity network flow environment. The approaches used in this research are offered as initial investigations toward the long-term goal of automated maintenance scheduling for a stochastic communication network. DTIC

MILLIMETER WAVE RADIOMETER UTILITY STUDY Final Report, May 1993 - Oct. 1994
Peter W. Gaiser, James P. Hollinger, Steven R. Highley, and Glenn D. Sandlin 27 Mar. 1995 105 p
(AD-A293811; NRL/MR/7220-95-7652) Avail: CASI HC A06/MF A02

Many military and environmental applications require wide area surveillance on a timely and global basis. Passive microwave and millimeter wave imaging has the advantage over visual and infrared systems of being a near all-weather surveillance system with the ability to see through clouds and most adverse weather conditions with equal day and night sensitivity. The major disadvantage of microwave and millimeter wave radiometric systems is that the relatively long wavelengths require aperture several orders of magnitude larger than at infrared to obtain comparable spatial resolution. However, even low resolution microwave and millimeter wave radiometers can contribute significantly to intelligence gathering and environmental remote sensing. This document presents a study of the capabilities of microwave and millimeter wave imaging from space with systems which provide resolutions of 100-400 m at observation frequencies of 1.4-140 GHz. Possible radiometer architectures and their space development are examined the surveillance and environmental remote sensing benefits of multifrequency high resolution microwave and millimeter wave radiometry are discussed in depth. TWO-DIMENSIONAL FINITE DIFFERENCE TIME DOMAIN (FD-TD) MODEL OF ELECTROMAGNETIC (EM) SCATTERING FROM A BURIED RECTANGULAR OBJECT Final Report, Jun. 1993 - Jun. 1994
Thomas A. Korjack Feb. 1995 36 p
(AD-A293685; ARL-TR-713) Avail: CASI HC A03/MF A01

A two-dimensional transverse-magnetic (TM) electromagnetic (EM) scattering problem from buried dielectric objects due to a Gaussian pulse is numerically solved using the Finite Difference Time Domain (FD-TD) method with absorbing boundary conditions via Maxwell's equations. The scatterers are rectangular cross sections in a multilayer media; the Gaussian pulse is reflected into a lossy earth by a finite, 450 plate that is part of the detector that receives the EM signal. Spatial distributions of electric field components are calculated over time for single and multiple land scatterers (mines). The scattered fields gradually diminish with time and are then eventually dissipated. Carpet plots are illustrated to depict the spatial distributions of the scattered field component at comparative time steps for one, two, and three distinct scatterers or land mines within the lossy media. Results clearly illustrate the typical wave patterns expected under the simulated conditions as presented in this report - i.e., conductivity (s) for the air is 0, conductivity for the earth is 0.01, conductivity for the grass is 0.005, and conductivity for the mines are 0, 0.02, and 0.008; permeability values ranged from 1 for air, 9 for earth, 5.5 for grass, and 2.3, 5.6, and 23.0 for the mines, respectively. Numerical analysis indicates that the difference of scattered signals between single and multiple scatterers are considerably obvious from the point of view of both time domain and frequency domain. COMPARISONS OF TARGET DETECTION CLUTTER USING DATA FROM THE 1993 FOPEN EXPERIMENTS
E. M. Winter, M. J. Schlangen, and C. R. Hendrickson Oct. 1994 13 p
(AD-A293052) Avail: CASI HC A03/MF A01

During 1993, a series of experiments were performed under the Advanced Research Projects Agency (ARPA) sponsorship using the SRI Ultra-Wide Band UHF Synthetic Aperture Radar (SAR). These experiments

were performed over a variety of clutter backgrounds to assess the foliage penetration capability of the technology and to investigate target detection in clutter. Experiments were conducted observing tropical rain forest backgrounds in Panama, several different desert backgrounds in the Yuma vicinity, and the mid-latitude temperate forest of Maine. SAR images were formed from the raw data using Differential GPS to aid in the focusing. The three locations represent different levels of foliage cover, ranging from the sparsely vegetated desert sites to the triple canopied rain forest. The characteristics of each site are discussed first through a presentation of photography and SAR imagery. The clutter characteristics are studied through a comparison of the cumulative distributions, which are plotted using a variety of conventions (e.g., log-normal, normal, Weibull). For each case, at least one reference target is included in the test scene. The signal of that target as processed by a common algorithm will be compared to the processed clutter distribution. DTIC

FOLDED COMPACT RANGE DEVELOPMENT AND COHERENT CHANGE DETECTION MEASUREMENT PROJECT
K. W. Sorensen Mar. 1995 82 p
(Contract DE-AC04-94AL-85000)
(DE95-009082; SAND-95-0389) Avail: CASI HC A05/MF A01

A novel, folded compact range configuration has been developed at the Sandia National Laboratories compact range antenna and radar cross section measurement facility, operated by the Radar/Antenna Department 2343, as a means of performing indoor, environmentally-controlled, far-field simulations of synthetic aperture radar (SAR) coherent change detection (CCD) measurements. This report describes the development of the folded compact range configuration, as well as the initial set of coherent change detection measurements made with the system. These measurements have been highly successful, and have demonstrated the viability of the folded compact range concept in simulating SAR CCD measurements. It is felt that follow-on measurements have the potential of contributing significantly to the body of knowledge available to the scientific community involved in CCD image generation and processing, and that this tool will be a significant aid in the research and development of change detection methodologies. REFLECTION AND TRANSMISSION OF ELECTROMAGNETIC PLANE WAVES FROM A UNIAXIAL CHIRO-OMEGA SLAB
P. K. Koivisto Jun. 1994 21 p
(PB95-206629; ISBN-951-22-2215-9) Avail: CASI HC A03/MF A01

Chiro-omega medium is a combination of the reciprocal chiral and omega media, and can be obtained by mixing helical and Omega-shaped wire elements in the host medium. In this article the most general uniaxial chiro-omega medium is studied. The solutions for the dispersion equations and corresponding eigenwaves are derived. Transmission and reflection properties of a chiro-omega slab at a normal incidence are studied, and the polarization, direction of the polarization ellipse, and relative powers of transmitted and reflected waves are given. The results are applied to find suitable parameters for designing a polarization transformer. These results are compared with those obtained in earlier studies on wave propagation in a free uniaxial chiral space, where the effect of the boundaries of a proposed polarization transforming device have been neglected. AUTOMATIC TARGET RECOGNITION (ATR): BACKGROUND STATISTICS AND THE DETECTION OF TARGETS IN CLUTTER M.S. Thesis
Nicholas Wager Dec. 1994 153 p
(AD-A293062) Avail: CASI HC A08/MF A02

This research investigated signal processing of two dimensional signals for the detection of targets in noise, particularly in complex background pattern noise. The researchers hypothesized that this type of noise was vulnerable to nonlinear processing. They investigated whether the human eye/brain acting as a surrogate for a nonlinear processor could outperform an optimum linear processor in a quantitative sense. The researchers did this by conducting computer experiments to determine the ability of an operator and an optimum linear filter to determine a known pattern's presence or absence in a noisy image. The performance of both the operator and optimum linear filter are recorded as probability of detection, probability of false alarm pairs, which the researchers use to determine effective signal-to-noise ratio. The performance of man versus machine (optimum linear filter) is compared quantitatively using the effective signal-to-noise ratio. Operator and machine/filter are tested against circular targets in random white gaussian noise and in satellite images. The researchers report that the machine filter outperforms the man when the details of both target and background are known in advance, but the man outperforms the machine/filter when the details are known only in a statistical sense. In this paper, a Ku-band portable SNG RF terminal using a flat antenna is proposed for making the best use of digital SNG systems. This portable terminal uses 16 planar microstrip subarray antennas, each with a solid-state power amplifier (SSPA) mounted on its rear. The proposed RF terminal is different from a conventional portable RF terminal with parabolic antenna in that it has electronic tracking capability. Electronic antenna tracking reduces time it takes to set up the terminal because precise alignment of the antenna is not required. The flat antenna meets the design objectives specified by the ITU-R Recommendations. The SSPA's have an efficiency of 21 percent and a power output of 5 W. The tracking performance of the feedback system which uses four subarrays, is also presented. Author

A BOUNDARY INTEGRAL EQUATION APPROACH TO THREE DIMENSIONAL ELECTROMAGNETIC WAVE SCATTERING PROBLEMS Ph.D. Thesis
Joseph Chiu Chao 1994 121 p
Avail: Univ. Microfilms Order No. DA9424201

Electromagnetic scattering models are finding increasing interest in many applications ranging from nondestructive evaluation (NDE) to design of optical systems. The availability of a computational scattering model characterizing the underlying system serves several purposes. First, it serves as an inexpensive test bed to simulate a variety of test situations. For instance, the forward model can be used to evaluate various polarizations and incidence angles of the incident source fields and the corresponding spatial distribution of the scattered fields which in turn provides information useful for optimizing the measurement of scattered fields. By preserving some of the realism that is usually possible in purely analytical methods, it provides valuable insight into the physics of actual problems. Second, forward scattering models are important in solving the inverse problem where the scattered fields are used for characterizing the size, the shape, and the constitution of the scatterer. The development of theoretical models largely relies on the use of numerical techniques such as boundary element method (BEM), finite element method (FEM), or finite difference method (FDM). However, no single numerical method has emerged as the optimal method for solving all electromagnetic scattering problems. One numerical method might be preferred over others, depending on the nature of the problem. For instance, problems which involve homogeneous scatterers and propagation of waves in an infinite medium are typically solved using the BEM whereas problems which involve a naturally truncated region are modeled using FEM and FDM. This dissertation presents a boundary integral equation (BIE) formulation for the problem of electromagnetic scattering due to homogeneous dielectric scatterers. The governing BIE's are then evaluated numerically using the BEM. Several fundamental electromagnetic scattering geometries are considered. The first problem involves solving for the scattered fields in the presence of a single, three dimensional, arbitrarily shaped, dielectric scatterer suspended in an infinite medium. The formulation is then extended to modeling the scattered fields in the presence of multiple dielectric scatterers as well as a dielectric scatterer in the proximity of an infinite perfect conducting plane. Lastly, the problem of a dielectric scatterer situated close to a dielectric half-space is discussed. The geometries are chosen so that the work presented in this dissertation

will serve as a basic model and solutions to a large range of problems can be obtained by modifying one or more of the configurations presented. Dissert. Abstr.

ADAPTIVE SPACE-TIME PROCESSING FOR AIRBORNE RADARS BASED ON DOPPLER PRE-PROCESSING
G. S. Liao, Z. Bao, and Y. Zhang 1994 9 p Sponsored by Institute of Scientific and Technical Information of China
(PB95-205464; ISTIC-TR-94245) Avail: Issuing Activity (National Technical Information Service (NTIS))

A new partial joint-domain spatial-temporal adaptive processing approach to airborne radars based on a pre-processing with a multi-channel Doppler filtering operation is proposed, assuming that the antenna is a rectangular planar array, in which the elements in each column are combined into a subarray. The principle and performance of the proposed processor are analyzed in detail, compared with those of two other processors. The excellent performance of the processor in the presence of large random amplitude and phase errors between the array elements is shown by theoretical analysis and computer simulation, particularly when targets are close to the mainlobe clutter. SCANNERLESS RANGE IMAGING WITH A SQUARE WAVE
Maritza R. Muguira, John T. Sackos, and Bart D. Bradley 1995 8 p Presented at the SPIE International Symposium on Aerospace/Defense Sensing and Dual-use Photonics, Orlando, FL, 17-21 Apr. 1995
(Contract DE-AC04-94AL-85000)
(DE95-009840; SAND-95-0721C; CONF-950472-6) Avail: CASI HC A02/MF A01

Scannerless range imaging (SRI) is a unique approach to three dimensional imaging without scanners. SRI does, however, allow a more powerful light source to be used as compared to conventional Laser Radar (LADAR) systems due to the speed of operation associated with this staring system. As a result, a more efficient method of operation was investigated. As originally conceived, SRI transmits a continuous intensity modulated sinusoidal signal; however, a square wave driver is more energy efficient than a sinusoidal driver. In order to take advantage of this efficiency, a square wave operational methodology was investigated. As a result, four image frames are required for the extraction of range using a square wave to unambiguously resolve all time delays within one time period compared to a minimum of three frames for the sinusoidal wave. (IFTR-7/1995) Avail: CASI HC A03/MF A01

This article describes a study of the changes which occur in the spectra of voiceless fricative consonants as a result of the proximity of a vowel and a consonant. The authors adopted spectrum level values sensed at different intervals and expressed as a 25-element vector as their basis for parameterization. Measurement results were subjected to discriminant analysis, which made it possible to determine the degree of similarity between the mean vectors representing different contexts. The authors discovered that neighboring vowels, especially /u/ and /i/, cause major changes in the spectra of fricatives, but this statement does not apply to all consonants. Among the fricatives they studied, /x/ exhibited the greatest proclivity for allophonization in a vowel context and the least proclivity for allophonization in a consonant context. This quarterly publication provides archival reports on developments in programs managed by JPL's Telecommunications and Mission Operations Directorate (TMOD), which now includes the former Telecommunications and Data Acquisition (TDA) Office. In space communications, radio navigation, radio science, and ground-based radio and radar astronomy, it reports on activities of the Deep Space Network (DSN) in planning, supporting research and technology, implementation, and operations. Also included are standards activity at JPL for space data and information systems and reimbursable DSN work performed for other space agencies through NASA. The preceding work is all performed for NASA's Office of Space Communications (OSC). For individual titles, see N95-32222 through N95-32240.

DETERMINATION OF THE POSITION OF JUPITER FROM RADIO METRIC TRACKING OF VOYAGER 1 **c91**
W. M. Folkner and R. J. Haw *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 1-8 (For primary document see N95-32221 11-32)
Avail: CASI HC A02/MF A03

The Voyager 1 spacecraft flew by Jupiter on March 5, 1979. Spacecraft navigation was performed with radio tracking data from NASA's Deep Space Network. In the years since then, there has been a great deal of progress in the definition of celestial reference frames and in determining the orbit and orientation of the Earth. Using these improvements, the radio metric range and Doppler data acquired from the Voyager 1 spacecraft near its encounter with Jupiter have been reanalyzed to determine the plane-of-sky position of Jupiter with much greater accuracy than was possible at the time of the encounter. The position of Jupiter at the time of encounter has been determined with an accuracy of 40 nrad in right ascension and 140 nrad in declination with respect to the celestial reference frame defined by the International Earth Rotation Service. This position estimate has been done to improve the ephemeris of Jupiter prior to the upcoming encounter of the Galileo spacecraft with Jupiter. Author

RATE CONSIDERATIONS IN DEEP SPACE TELEMETRY **c17**
M. Costa, M. Belongie, and F. Pollara *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 9-15 (For primary document see N95-32221 11-32)
Avail: CASI HC A02/MF A03

The relationship between transmission rate and source and channel signal-to-noise ratios (SNR's) is discussed for the transmission of a Gaussian source over a binary input, additive Gaussian channel, with a mean-squared distortion criterion. We point out that for any finite rate, and sufficiently high channel SNR, the fidelity criterion (reproduction SNR) is upper bounded by a function of the transmission rate. Thus, the performance becomes

rate limited rather than power limited. This effect is not observed with the binary symmetric source, the binary-input Gaussian channel combination, or the Gaussian source, unconstrained-input Gaussian channel combination. Author

AN EFFICIENT IMPLEMENTATION OF FORWARD-BACKWARD LEAST-MEAN-SQUARE ADAPTIVE LINE ENHANCERS **c33**

H.-G. Yeh and T. M. Nguyen *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 16-26 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

An efficient implementation of the forward-backward least-mean-square (FBLMS) adaptive line enhancer is presented in this article. Without changing the characteristics of the FBLMS adaptive line enhancer, the proposed implementation technique reduces multiplications by 25% and additions by 12.5% in two successive time samples in comparison with those operations of direct implementation in both prediction and weight control. The proposed FBLMS architecture and algorithm can be applied to digital receivers for enhancing signal-to-noise ratio to allow fast carrier acquisition and tracking in both stationary and nonstationary environments. COMPUTER SIMULATION RESULTS FOR PCM/PM/NRZ RECEIVERS IN NONIDEAL CHANNELS **c17**

A. Anabtawi, T. M. Nguyen, and S. Million *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 27-53 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

This article studies, by computer simulations, the performance of deep-space telemetry signals that employ the pulse code modulation/phase modulation (PCM/PM) technique, using nonreturn-to-zero data, under the separate and combined effects of unbalanced data, data asymmetry, and a band-limited channel. The study is based on measuring the symbol error rate performance and comparing the results to the theoretical results presented in previous articles. Only the effects of imperfect carrier tracking due to an imperfect data stream are considered. The presence of an imperfect data stream (unbalanced and/or asymmetric) produces undesirable spectral components at the carrier frequency, creating an imperfect carrier reference that will degrade the performance of the telemetry system. Further disturbance to the carrier reference is caused by the intersymbol interference created by the band-limited channel. Author

THE APPLICATION OF NONCOHERENT DOPPLER DATA TYPES FOR DEEP SPACE NAVIGATION **c17**

S. Bhaskaran *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 54-65 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

Recent improvements in computational capability and DSN technology have renewed interest in examining the possibility of using one-way Doppler data alone to navigate interplanetary spacecraft. The one-way data can be formulated as the standard differenced-count Doppler or as phase measurements, and the data can be received at a single station or differenced if obtained simultaneously at two stations. A covariance analysis, which analyzes the accuracy obtainable by combinations of one-way Doppler data, is performed and compared with similar results using standard two-way Doppler and range. The sample interplanetary trajectory used was that of the Mars Pathfinder mission to Mars. It is shown that differenced one-way data are capable of determining the angular position of the spacecraft to fairly high accuracy, but have relatively poor sensitivity to the range. When combined with single-station data, the position dispersions are roughly an order of magnitude larger in range and comparable in angular position as compared to dispersions obtained with standard two-way data types. It was also found that the phase formulation is less sensitive to data weight variations and data coverage than the differenced-count Doppler formulation. Author

DEGRADATION IN FINITE-HARMONIC SUBCARRIER DEMODULATION

Y. Feria, S. Townes, and T. Pham *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 78-86 (For primary document see N95-32221 11-32)

Avail: CASI HC A02/MF A03

Previous estimates on the degradations due to a subcarrier loop assume a square-wave subcarrier. This article provides a closed-form expression for the degradations due to the subcarrier loop when a finite number of harmonics are used to demodulate the subcarrier, as in the case of the buffered telemetry demodulator. We compared the degradations using a square wave and using finite harmonics in the subcarrier demodulation and found that, for a low loop signal-to-noise ratio, using finite harmonics leads to a lower degradation. The analysis is under the assumption that the phase noise in the subcarrier (SC) loop has a Tikhonov distribution. This assumption is valid for first-order loops. Author

TOWARDS OPTIMUM DEMODULATION OF BANDWIDTH-LIMITED AND LOW SNR SQUARE-WAVE SUBCARRIER SIGNALS

Y. Feria and W. Hurd *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 87-95 (For primary document see N95-32221 11-32)

Avail: CASI HC A02/MF A03

The optimum phase detector is presented for tracking square-wave subcarriers that have been bandwidth limited to a finite number of harmonics. The phase detector is optimum in the sense that the loop signal-to-noise ratio (SNR) is maximized and, hence, the rms phase tracking error is minimized. The optimum phase detector is easy to implement and achieves substantial improvement. Also presented are the optimum weights to combine the signals demodulated from each of the harmonics. The optimum weighting provides SNR improvement of 0.1 to 0.15 dB when the subcarrier loop SNR is low (15 dB) and the number of harmonics is high (8 to 16).

ENHANCED DECODING FOR THE GALILEO LOW-GAIN ANTENNA MISSION: VITERBI REDECODING WITH FOUR DECODING STAGES

S. Dolinar and M. Belongie *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 96-109 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

The Galileo low-gain antenna mission will be supported by a coding system that uses a (14,1/4) inner convolutional code concatenated with Reed-Solomon codes of four different redundancies. Decoding for this code is designed to proceed in four distinct stages of Viterbi decoding followed by Reed-Solomon decoding. In each successive stage, the Reed-Solomon decoder only tries to decode the highest redundancy codewords not yet decoded in previous stages, and the Viterbi decoder redecodes its data utilizing the known symbols from previously decoded Reed-Solomon codewords. A previous article analyzed a two-stage decoding option that was not selected by Galileo. The present article analyzes the four-stage decoding scheme and derives the near-optimum set of redundancies selected for use by Galileo. The performance improvements relative to one- and two-stage decoding systems are evaluated. Author

TESTING THE PERFORMANCE OF FEEDBACK CONCATENATED DECODER WITH A NONIDEAL RECEIVER

Y. Feria and S. Dolinar *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 110-130 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

One of the inherent problems in testing the feedback concatenated decoder (FCD) at our operating symbol signal-to-noise ratio (SSNR) is that the bit-error rate is so low that we cannot measure it directly through simulations in a reasonable time period. This article proposes a test procedure that will give a reasonable estimate of the expected losses even though the number of frames tested is much smaller than needed for a direct measurement. This test procedure provides an organized robust methodology for extrapolating small amounts of test data to give reasonable estimates of FCD loss increments at unmeasurable miniscule error rates. Using this test procedure, we have run some preliminary tests on the FCD to quantify the losses due to the fact that the input signal contains multiplicative non-white non-Gaussian noises resulting from the buffered telemetry demodulator (BTD). Besides the losses in the BTD, we have observed additional loss increments of 0.3 to 0.4 dB at the output of the FCD for several test cases with loop signal-to-noise ratios (SNR's) lower than 20 dB. In contrast, these loss increments were less than 0.1 dB for a test case with the subcarrier loop SNR at about 28 dB. This test procedure can be applied to more extensive test data to determine thresholds on the loop SNRs above which the FCD will not suffer substantial loss increments. Author

PERFORMANCE OF RESIDUAL CARRIER ARRAY-FEED COMBINING IN CORRELATED NOISE

H. H. Tan *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 131-147 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

An array feed combining system for the recovery of signal-to-noise ratio (SNR) loss due to antenna reflector deformation has been implemented and is currently being evaluated on the Jet Propulsion Laboratory's 34-meter DSS-13 antenna. In this system, the defocused signal field captured by a focal plane array feed is recovered using real-time signal-processing and signal-combining techniques. The current signal-processing and signal-combining algorithms are optimum under the assumption that the white Gaussian noise processes in the received signals from different array elements are mutually uncorrelated. Experimental data at DSS 13 indicate that these noise processes are indeed mutually correlated. The main result of this article is an analytical derivation of the actual SNR performance of the current suboptimal signal-combining algorithm in this correlated-noise environment. The analysis here shows that the combined signal SNR can either be improved or degraded depending on the relation between the array signal and noise correlation coefficient phases. Further performance improvement will require the development of signal-combining methods that take into account the correlated noises. Author

TRELLIS COMPLEXITY BOUNDS FOR DECODING LINEAR BLOCK CODES

A. B. Kiely, S. Dolinar, L. Ekroot, R. J. McEliece (California Inst. of Tech., Pasadena, CA.), and W. Lin (California Inst. of Tech., Pasadena, CA.) *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 159-172 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

We consider the problem of finding a trellis for a linear block code that minimizes one or more measures of trellis complexity. The domain of optimization may be different permutations of the same code or different codes with the same parameters. Constraints on trellises, including relationships between the minimal trellis of a code and that of the dual code, are used to derive bounds on complexity. We define a partial ordering on trellises: If a trellis is optimum with respect to this partial ordering, if has the desirable property that it simultaneously minimizes all of the complexity measures examined. We examine properties of such optimal trellises and give examples of optimal permutations of codes, most notably the (48,24,12) quadratic residue code. Author

RESIDUAL AND SUPPRESSED-CARRIER ARRAYING TECHNIQUES FOR DEEP-SPACE COMMUNICATIONS

M. Shihabi, B. Shah, S. Hinedi, and S. Million *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 173-201 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

Three techniques that use carrier information from multiple antennas to enhance carrier acquisition and tracking are presented. These techniques in combination with baseband combining are analyzed and simulated for residual and suppressed-carrier modulation. It is shown that the carrier arraying using a single carrier loop technique can acquire and track the carrier even when any single antenna in the array cannot do so by itself. The carrier aiding and carrier arraying using multiple carrier loop techniques, on the other hand, are shown to lock on the carrier only when one of the array elements has sufficient margin to acquire the carrier on its own. A HIGH-SPEED PHOTONIC CLOCK AND CARRIER REGENERATOR **c35**

X. S. Yao and G. Lutes *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 202-210 (For primary document see N95-32221 11-32)

Avail: CASI HC A02/MF A03

As data communications rates climb toward 10 Gbits/s, clock recovery and synchronization become more difficult, if not impossible, using conventional electronic circuits. The high-speed photonic clock regenerator described in this article may be more suitable for such use. This photonic regenerator is based on a previously reported photonic oscillator capable of fast acquisition and synchronization. With both electrical and optical clock inputs and outputs, the device is easily interfaced with fiber-optic systems. The recovered electrical clock can be used locally and the optical clock can be used anywhere within a several kilometer radius of the clock/carrier regenerator. Author

EFFECTS OF CORRELATED NOISE ON THE FULL-SPECTRUM COMBINING AND COMPLEX-SYMBOL COMBINING ARRAYING TECHNIQUES

P. Vazirani *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 211-241 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

The process of combining telemetry signals received at multiple antennas, commonly referred to as arraying, can be used to improve communication link performance in the Deep Space Network (DSN). By coherently adding telemetry from multiple receiving sites, arraying produces

an enhancement in signal-to-noise ratio (SNR) over that achievable with any single antenna in the array. A number of different techniques for arraying have been proposed and their performances analyzed in past literature. These analyses have compared different arraying schemes under the assumption that the signals contain additive white Gaussian noise (AWGN) and that the noise observed at distinct antennas is independent. In situations where an unwanted background body is visible to multiple antennas in the array, however, the assumption of independent noises is no longer applicable. A planet with significant radiation emissions in the frequency band of interest can be one such source of correlated noise. For example, during much of Galileo's tour of Jupiter, the planet will contribute significantly to the total system noise at various ground stations. This article analyzes the effects of correlated noise on two arraying schemes currently being considered for DSN applications: full-spectrum combining (FSC) and complex-symbol combining (CSC). A framework is presented for characterizing the correlated noise based on physical parameters, and the impact of the noise correlation on the array performance is assessed for each scheme. Author

A SEISMIC DATA COMPRESSION SYSTEM USING SUBBAND CODING

A. B. Kiely and F. Pollara *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 242-251 (For primary document see N95-32221 11-32)

Avail: CASI HC A02/MF A03

This article presents a study of seismic data compression techniques and a compression algorithm based on subband coding. The algorithm includes three stages: a decorrelation stage, a quantization stage that introduces a controlled amount of distortion to allow for high compression ratios, and a lossless entropy coding stage based on a simple but efficient arithmetic coding method. Subband coding methods are particularly suited to the decorrelation of nonstationary processes such as seismic events. Adaptivity to the nonstationary behavior of the waveform is achieved by dividing the data into separate blocks that are encoded separately with an adaptive arithmetic encoder. This is done with high efficiency due to the low overhead introduced by the arithmetic encoder in specifying its parameters. The technique could be used as a progressive transmission system, where successive refinements of the data can be requested by the user. This allows seismologists to first examine a coarse version of waveforms with minimal usage of the channel and then decide where refinements are required. Rate-distortion performance results are presented and comparisons are made with two block transform methods. Author

DSS-24 MICROWAVE HOLOGRAPHY MEASUREMENTS **c35**

D. J. Rochblatt, P. M. Withington, and H. J. Jackson *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 252-270 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

The JPL DSN Microwave Antenna Holography System (MAHST) was applied to the newly constructed DSS-24 34-m beam-waveguide antenna at Goldstone, California. The application of MAHST measurements and corrections at DSS 24 provided the critical RF performance necessary to not only meet the project requirements and goals, but to surpass them. A performance increase of 0.35 dB at X-band (8.45 GHz) and 4.9 dB at Ka-band (32 GHz) was provided by MAHST, resulting in peak efficiencies of 75.25 percent at X-band and 60.6 percent at Ka-band (measured from the Cassegrain focus at f1). The MAHST enabled setting the main reflector panels of DSS 24 to 0.25-mm rms, making DSS 24 the highest precision antenna in the NASA/JPL DSN. The precision of the DSS-24 antenna (diameter/rms) is 1.36 x 10(exp 5), and its gain limit is at 95 GHz. Author

DIGITAL SIGNAL PROCESSING IN THE RADIO SCIENCE STABILITY ANALYZER

C. A. Greenhall *In its* The Telecommunications and Data Acquisition Report 15 May 1995 p 271-288 (For primary document see N95-32221 11-32)

Avail: CASI HC A03/MF A03

The Telecommunications Division has built a stability analyzer for testing Deep Space Network installations during flight radio science experiments. The low-frequency part of the analyzer operates by digitizing wave signals with bandwidths between 80 Hz and 45 kHz. Processed outputs include spectra of signal, phase, amplitude, and differential phase; time series of the same quantities; and Allan deviation of phase and differential phase. This article documents the digital signal-processing methods programmed into the analyzer. Author

THE DYNAMIC RANGE OF RADAR SIGNAL GENERATION IN THE MSS-2 SIMULATION FACILITY Final Report

Chris Bishop Mar. 1995 79 p

(AD-A293856; AMSMI/RD-TR-CR-SS-95-10) Avail: CASI HC A05/MF A01

The dynamic range of radar signal generation in the MSS-2 affects the types of targets and environments which the MSS-2 facility can simulate. Only the power handling capability of the facility limits the maximum size of large targets; however, assessing the ability of the MSS-2 to produce very small targets is quite difficult and depends on the characteristics of the device under test. This report addresses the issues which limit minimum target size and calculations the dynamic range of the radar signal generation equipment in the MSS-2 given a typical seeker. DTIC

MATERIALS WITH CONTROLLABLE SIGNATURE PROPERTIES [MATERIAL MED STYRBARA SIGNATUREGENSKAPER]

O. Dickman, B. Holmberg, T. Karlsson, and S. Savage Feb. 1995 28 p In SWAHILI

(PB95-222964; FOA-R-95-00093-2.4-SE) Avail: Issuing Activity (National Technical Information Service (NTIS))

We have in this report considered some types of material with potential for use in signature control of structures. The material types selected for inclusion in this study were electrically conductive polymers, fullerenes, nanostructured materials and Langmuir-Blodgett films. To control the signature of a structure in real time it must be possible to vary the material emissivity, structural transmission, and reflection or absorption of electromagnetic radiation in the relevant wavelength region. This may be achieved by changes in temperature, pressure, electrical or magnetic field or by the concentration of a chemical substance within the material. It is concluded that it is feasible to develop electrically conductive polymeric materials with controllable properties for practical signature control application within 5 to 10 years. NTIS

POINT REFLECTOR MODEL FOR THE SIMULATION OF RADAR TARGET GLINT AND DOPPLER PHENOMENA [PUNKTREFLEKTORMODELL FOER SIMULERING AV RADARMALS GLINT- OCH DOPPLEREGENSKAPER]

H. Grubeck Feb. 1995 44 p In SWAHILI

(PB95-222980; FOA-R-94-00025-3.3-SE) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report describes the mathematics of a radar model for the simulation of glint and Doppler phenomena. Glint is an unwanted phenomenon, which

deteriorates radar tracking performance. The term denotes a fluctuation of the target direction, experienced by a radar, tracking a complex target. Doppler shift refers to the frequency change of a radar wave, due to the reflection against a moving target. It can be used by modern so-called coherent radar systems for velocity determination. A three-dimensional space is modeled, containing a rigid body of point scattering reflectors (the target) and a point of measuring (the radar). The target and the radar can move freely and independently in the space. The movement of the target and the radar is described with a number of coordinate systems, which are presented in this report. Some simple simulations are also presented in this report. A simulation tool is available for interested users and the purpose of this report is to announce its existence. The program is written in MATLAB Simulink. NTIS

Use of high-temperature superconductors (HTS's) for current leads to deliver power to devices at liquid helium temperature can reduce refrigeration requirements to values significantly below those achievable with conventional leads. HTS leads are now near commercial realization. Argonne National Laboratory (ANL) has developed a sinter-forge process to fabricate current leads from bismuth-based superconductors. The current-carrying capacity of these leads is five times better than that of HTS leads made by a conventional fabrication process. ANL along with Superconductivity, Inc., has developed a 1500 ampere current lead for an existing superconducting magnetic energy storage (SMES) device. With Babcock & Wilcox Company, Argonne is creating 16-kiloampere leads for use in a 0.5 MWh SMES. In a third project Argonne performed characterization testing of a existing, proprietary conduction-cooled lead being developed by Zer Res Corp. DOE

WORLDWIDE INTERCOMPARISON OF IMPULSE VOLTAGE MEASURING SYSTEMS AT 600 kV LEVEL
M. Aro, J. Haellstroem, and M. L. Pykaelae 30 Nov. 1994 105 p
(PB95-195574; TKK-SJT-16) Avail: CASI HC A06/MF A02

Nine laboratories participated the intercomparison. Laboratories compared their impulse voltage measuring systems (one or several) to the circulating measuring system at voltage levels of 300 and 600 kV and with different impulse shapes, i.e. with full smooth, front-chopped (0.5 micro sec), sliced (MOA load) and oscillating impulse at both positive and negative polarities. The circulating measuring system was a complete system consisting of 10 kiloohm 700 kV resistive voltage divider, h.v. lead, damping resistor, measuring cable, terminator and peak voltmeter. For the first time

in intercomparisons with impulse voltages, together with similar parallel intercomparison in Europe, the circulating system was a complete system including also the l.v. cable and instrument. Both peak values and time parameters were compared. However, the former has larger significance, because the circulating system was complete for that measurement only. At the time it was not feasible to circulate any digital recorder. The measurements were performed during two years between October 1991 and January 1993. The results are generally good both in peak value and time parameter comparisons with all of the used impulse shapes. NTIS

(Contract DAJA45-93-C-0017)
(AD-A291487; R/D-6980-EE-01) Avail: CASI HC A02/MF A01

The present report provides an account of the embedding of a composite material transducer within an E-glass reinforced epoxy laminate structure for use as an in-situ AE sensor, strain gauge, or ultrasonic detector 1 transmitter for NDT (nondestructive testing) techniques. It is envisaged that by embedding a transducer within a structure it may be used as an 'early warning' device, which would warn against potential failure of the structure. Another way of thinking is that the transducer while being used in a sensing mode can then be used in an actuating mode by use of a feedback circuit thus for example being used to damp out any unwanted vibrations of the structure. EMC REQUIREMENTS FOR TYPE APPROVAL OF MARINE ELECTRONICS. NORDTEST PROJECT 1157-94
L. Bergsten and P. Guldbrandsen 1994 40 p
(PB95-211330; SP-RAPP-1994:50) Avail: CASI HC A03/MF A01

Marine electronic equipment is tested according to the requirements of several ship classification societies. Testing is also carried out as specified in military standards. The ship classification requirements are similar to each other but not identical, while the military requirements often significantly differ from the commercial ones and will not be treated in this report. The European Union (EU) directive on electromagnetic compatibility (EMC) is applicable to marine electronics but no EN standard is available and there are no plans to come up with one. A manufacturer who wants to have his equipment approved according to the requirements as mentioned above will have difficulties in writing a test program that covers all relevant requirements. An overview is therefore needed of a common test specification that is accepted by all classification societies. NTIS

DEVELOPMENT OF A METHOD FOR MEASUREMENT OF TRIBOELECTRIC CHARGING
A. Boerjesson and S. Byheden 1994 46 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-211322; SP-RAPP-1994:34) Avail: CASI HC A03

A method for measurement of triboelectric charging has been defined. The principle of the method is measurement by an electrostatic voltmeter of the voltage developed on a test piece after a roll has rolled over it. The roll materials used are quartz and teflon respectively. Other materials can be used but are not verified in this work. The method is evaluated to give a repeatability when measuring electrostatic conductive foils to better than +/- 10%. This figure includes spread in the test item itself. Before being proposed as a standard, the method has to be further evaluated. Comparative measurements (Round Robin tests) should be performed by other laboratories to evaluate the reproducibility of the method. NTIS

A SIMPLE MODEL FOR THE DC FLUX TRANSFORMER IN LAYERED SUPERCONDUCTORS WITH JOSEPHSON COUPLING
K. K. Uprety and D. Dominguez (Los Alamos National Lab., NM.) Sep. 1994 30 p
(DE95-614468; IC-94/291) Avail: CASI HC A03/MF A01 (US Sales Only)

We present a model for the dc flux transformer configuration in layered superconductors with Josephson coupling. It consists of a simple extension of a model introduced by Clem for the traditional dc flux transformer, but including Josephson coupling and dissipation between planes. We calculate the non-linear current-voltage characteristics for different cases. We find two kinds of behaviour. For weak pinning or strong interplane coupling (both due to magnetic forces and Josephson effect) there is an onset of dissipation with the same voltages in both the top and the bottom faces of the sample, at a given critical current. At a higher current there is a decoupling of the two faces where they have different voltages. This corresponds to a cutting of the vortices that occurs between the first (top) and the second planes. The decoupling current is independent of pinning and vanishes linearly with temperature close to T(c). For strong pinning or weak interplane coupling, each face behaves independently with corresponding different critical currents for the onset of dissipation and different voltages. DOE

A THEORETICAL ANALYSIS OF STEADY-STATE PHOTOCURRENTS IN SIMPLE SILICON DIODES
L. Edmonds Mar. 1995 151 p
(Contract NAS7-1260)
(NASA-CR-198885; JPL-Publ-95-10; NAS 1.26:198885) Avail: CASI HC A08/MF A02

A theoretical analysis solves for the steady-state photocurrents produced by a given photo-generation rate function with negligible recombination in simple silicon diodes, consisting of a uniformly doped quasi-neutral region (called 'substrate' below) adjacent to a p-n junction depletion region (DR). Special attention is given to conditions that produce 'funneling' (a term used by the single-eventeffects community) under steady-state conditions. Funneling occurs when carriers are generated so fast that the DR becomes flooded and partially or completely collapses. Some or nearly all of the applied voltage, plus built-in potential normally across the DR, is now across the substrate. This substrate voltage drop affects substrate currents. The steady-state problem can provide some qualitative insights into the more difficult transient problem. First, it was found that funneling can be induced from a distance, i.e., from carriers generated at locations outside of the DR. Secondly, it was found that the substrate can divide into two subregions, with one controlling substrate resistance and the other characterized by ambipolar diffusion. Finally, funneling was found to be more difficult to induce in the p(sup +)/n diode than in the n(sup +)/p diode. The carrier density exceeding the doping density in the substrate and at the DR boundary is not a sufficient condition to collapse a DR. Author

PRE-AMPLIFIER WITH MULTI-STAGE FEEDBACK Patent
James D. Hagerty, inventor (to Navy) 6 Dec. 1994 7 p Filed 22 Mar. 1994
(AD-D017371; US-Patent-5,371,479; US-Patent-Appl-SN-215879; US-Patent-Class-330-294) Avail: US Patent and Trademark Office

A circuit for amplifying an input signal comprises an operational amplifier, a dual operational amplifier, and a buffering operational amplifier all cascaded in the afore-mentioned order. The first operational amplifier amplifies the input signal with minimum noise degradation, is set up as a non-inverting amplifier stage, and has a local negative feedback loop comprising a resistor and capacitor in parallel. The dual operational amplifier has two amplifying devices. One device forms a second amplifying stage which increases the gain of the pre-amplified input signal and has a local negative feedback loop comprising a resistor. The other device is a third operational amplifier which combines with the buffering operational amplifier to form an amplifying and buffering stage. The third operational amplifier connects in series to the output of the second amplifying stage. The buffering operational amplifier connects in series to the output of the third operational amplifier and buffers the amplified signal at this output. The amplifying and buffering stage has a two-stage feedback loop comprising a resistor connected between the output of the buffering operational amplifier and the inventing input of the third operational amplifier. A four-stage feedback loop includes a resistor and capacitor in parallel and connects between the output of the buffering operational amplifier and the inverting input of the first operational amplifier. FRACTAL QUANTUM WELL HETEROSTRUCTURES FOR BROADBAND LIGHT EMITTERS
M. H. Crawford, P. L. Gourley, K. E. Meissner, M. B. Sinclair, E. D. Jones, W. W. Chow, and R. P. Schneider, Jr. 1994 11 p Presented at the SPIE 1995 Conference on Optics, Electro-optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract DE-AC04-94AL-85000)
(DE95-009579; SAND-94-2169C; CONF-950226-31) Avail: CASI HC A03/MF A01

We examine carrier relaxation and radiative recombination in AlGaAs based near IR and AlGaInP based visible fractal quantum well heterostructures. Through temperature dependent photoluminescence, we demonstrate that enhanced population of higher lying energy levels can be achieved by varying the thickness of the layers in the fractal heterostructure. This distribution of carriers results in room temperature emission over a relatively broad range of wavelengths: approximately 700-855 nm for AlGaAs structures and 575-650 nm for AlGaInP structures. Spectra are compared to theoretical calculations to evaluate the non-equilibrium nature of the carrier distributions. Time resolved photoluminescence measurements demonstrate an approximately linear relationship between the radiative decay time and the layer thickness of the structure. Correspondingly, integrated luminescence measurements at room temperature reveal a factor of four increase in the light output efficiency of the structure as the fractal layer thickness is increased from 50 to 400 angstrom. The applicability of these heterostructures to broadband LED's is discussed. DOE

NEURAL NETWORK FALSE ALARM FILTER, VOLUME 2 Final Report, Sep. 1992 - Sep. 1994
F. Aylstock, L. Elerin, J. Hintz, C. Learoyd, and R. Press Dec. 1994 91 p
(Contract F30602-92-C-0065)
(AD-A293114; RL-TR-94-216-Vol-2) Avail: CASI HC A05/MF A01

This effort identified, developed, and demonstrated a set of approaches for applying neural network learning techniques to the development of a real-time built-in test (BIT) capability to filter out false-alarms from the BIT output. Following a state-of-the-art assessment, a decision space of 19 neural network models, 9 fault report causes, and 12 common groups of BIT techniques was identified. From this space, four unique, high-potential combinations were selected for further investigation. These techniques were subsequently simulated for application to a MILSATCOM system. Detailed analyses of their strengths and weaknesses were performed along with cost/benefit analyses. This study concluded that the best candidates for neural network insertion are new systems where neural network requirements can be included in the initial system design and that a major challenge is the availability of real data for training of the networks. Volume 1 of this report documents the activities and findings of the effort, including an extensive, annotated bibliography. Volume 2 contains a tutorial overview of the neural networks, BIT techniques, and false alarm causes utilized in the final phases of this study. DTIC

DECIMATION OF ENCODING ERRORS IN AN OPTIMUM SNS 2 MICRON LOW-NOISE CMOS ADC M.S. Thesis
Jeffrey L. Schafer Mar. 1995 202 p
(AD-A293208) Avail: CASI HC A10/MF A03

Significant research in high performance analog-to-digital converters (ADC's) has been directed at retaining part of the high-speed flash ADC architecture, while reducing the total number of comparators in the circuit. The symmetrical number system (SNS) can he used to preprocess the analog input signal, reducing the number of comparators and thus reducing the chip area and power consumption of the ADC. This thesis examines the issue of encoding errors that result when the separate channels m sub i are brought together to derive the input analog voltage. The Very Large Scale Integrated (VLSI) design for the comparators, error checking circuits and Programmable Logic Arrays (PLA's) use the Orbit 2 Micron CMOS N-well double-metal, double-poly fabrication process. Steady state transfer functions are shown which detail encoding errors that occur when the folded input samples lie at one of the code transition points. To discard the encoding errors that occur, a decimation band is constructed at each transition Point The effectiveness of the decimation band in eliminating the encoding errors and the linearity error is quantified. An Application Specific Integrated Circuit (ASIC) is designed. DTIC

This document describes the electrical short circuit and current overload tests that were conducted on wires used in commercial transport category aircraft. This testing was conducted to evaluate the fire potential that may result from electrical faults. Results of this testing showed that circuit breakers provide reliable overcurrent protection and that circuit breakers may not protect wire from ticking faults but can protect wire from direct shorts. It also showed that circuit breakers may not safeguard against the ignition of flammable materials by ticking faults. Preliminary testing also indicated that direct short circuits are not likely to start a fire and that direct short circuits do not erode insulation and conductors to the same degree that ticking faults do. Current overload testing that resulted in complete thermal degradation of the wire was also conducted to compare it with a fire-exposed wire. No differences were seen; however, the conductor of the wire subjected to the fire was more brittle than the current overloaded wire. Further testing along with metallurgical evaluation would be necessary to substantiate this finding fully. DTIC

MOBILE ELECTRIC POWER Final Report
David P. Bloomfield, Valerie J. Bloomfield, Paul D. Grosjean, and James W. Kelland 28 Feb. 1995 46 p
(Contract DAAL03-92-C-0041)
(AD-A292721; ARO-30066.1-CH-SB2) Avail: CASI HC A03/MF A01

The objective of this program was to develop a mobile fuel cell power supply for use by soldiers. The Century Series of 100 through 500 watt fuel cell power supplies was developed. The Century Series fuel cell power supplies are made up of a fuel cell stack, chemical hydride hydrogen supply, a fan and a controller. The FC-200, the 200 watt Century Series power supply, weighs 8.8 lb. and has a volume of 322 cu in. The operating point is 0.7 volt/cell at 125 ASF; a power density of 22.7 watts/cu in. or 0.62 watts/cu in. and an energy density of 110 whr/lb. The prototype 750 whr hydrogen supply weighs 7 lbs. and has a volume of 193 cu in. The

fuel elements weigh 0.45 lb. and require 0.79 lbs. of water. The FC-200 has powered a scooter requiring a starting current of three times the rated current of the stack. It has also powered a microclimate cooler. DTIC

OPTIMIZATION OF HIGH-TEMPERATURE SUPERCONDUCTOR CURRENT LEADS
S. Y. Seol (Chonnam National Univ., Kwangju, Republic of Korea.), J. R. Hull, and M. C. Chyu (Texas Technological Univ., Lubbock, TX.) 1995 5 p Presented at the Applied Superconductivity Conference, Boston, MA, 16-21 Oct. 1994
(Contract W-31-109-eng-38)
(DE95-005838; ANL/ET/CP-82190; CONF-941013-31) Avail: CASI HC A01/MF A01

Methods to improve the performance of high-temperature superconducting current leads are analyzed. Designs are considered that are inherently safe from burnup, even if the lead enters the normal state. The effect of a tapered lead that takes advantage of the increase in critical current density with decreasing temperature will decrease helium boiloff by about a factor of two for an area ratio of four. A new concept, in which Ag powder is distributed in increasing concentration from the cold end to the hot end of the lead in sintered YBCO, is shown to have comparable performance to that of leads made with Ag-alloy sheaths. Performance of the best inherently safe designs is about one order of magnitude better than that of optimized nonsuperconducting leads. BSCCO leads with Ag-alloy sheaths show improved performance for Au fractions up to about 3%, after which increases in Au fraction yield negligible performance improvement. DOE

PERFORMANCE EVALUATION OF HIGH-TEMPERATURE SUPERCONDUCTING CURRENT LEADS FOR MICRO-SMES SYSTEMS
R. C. Niemann, Y. S. Cha, J. R. Hull, W. E. Buckles (Superconductivity, Inc., Madison, WI.), B. R. Weber (Superconductivity, Inc., Madison, WI.), and S. T. Yang (Wisconsin Univ., Madison, WI.) 1995 5 p Presented at the Applied Superconductivity Conference, Boston, MA, 16-21 Oct. 1994
(Contract W-31-109-eng-38)
(DE95-005843; ANL/ET/CP-84477; CONF-941013-32) Avail: CASI HC A01/MF A01

As part of the U.S. Department of Energy's Superconductivity Technology Program, Argonne National Laboratory and Superconductivity, Inc., are developing high-temperature superconductor (HTS) current leads for application to micro-SMES systems. Two 1500-A HTS leads have been designed and constructed. A component performance evaluation program was conducted to confirm performance predictions and/or to qualify the design features for construction. The evaluations included HTS characteristics, demountable electrical connections, and heat intercept effectiveness. The performance of current lead assemblies is being evaluated in a zero-magnetic-field test program that included assembly procedures, tooling, and quality assurance; thermal and electrical performance; and flow and mechanical characteristics. The leads were installed in a liquid helium test cryostat and connected at their cold ends by a current jumper. The leads were heat intercepted with a cryocooler. DOE

EXPERIMENTAL INVESTIGATION OF THE EFFECTIVENESS OF FLOW-THROUGH MODULES FOR ELECTRONICS COOLING M.S. Thesis
William G. Plott Dec. 1994 118 p
(AD-A293284) Avail: CASI HC A06/MF A02

The heat transfer characteristics and performance capabilities of a liquid flow-through module for electronics cooling were investigated experimentally using the Standard Electronics Module, format 'E' (SEM-E) size module. Brayco Micronic 889, a dielectric polyalphaolefin, was tested as the coolant. One surface of the flow-through module was populated with six etched foil heaters placed on the module over the fluid flow path. With thermocouples affixed to the surface and placed in the inlet and outlet tubing, data was gathered and analyzed to quantity module effectiveness in dissipating heat over a variety of power input settings and coolant flow rates. The research area for this project is the mode competition and multi-frequency effects on high power fast wave devices. Specifically: (1) high power gyrotrons for plasma heating; (2) parametric mode interactions in harmonic gyrotrons; (3) multi-frequency effects in fel oscillators; and (4) modeling of harmonic gyroklystrons, phase locked gyro oscillators, and gyro-twystrons. The time dependent multi-mode simulation code, MAGY, is being used for the nonlinear simulation of high power gyrotrons.

THE ART AND SCIENCE OF MAGNET DESIGN: SELECTED NOTES OF KLAUS HALBACH, VOLUME 2
Feb. 1995 262 p
(Contract DE-AC03-76SF-00098)
(DE95-008450; LBL-PUB-755) Avail: CASI HC A12/MF A03

This volume contains a compilation of 57 notes written by Dr. Klaus Halbach selected from his collection of over 1650 such documents. It provides an historic snapshot of the evolution of magnet technology and related fields as the notes range from as early as 1965 to the present, and is intended to show the breadth of Dr. Halbach's interest and ability that have long been an inspiration to his many friends and colleagues. As Halbach is an experimental physicist whose scientific interests span many areas, and who does his most innovative work with pencil and paper rather than at the workbench or with a computer, the vast majority of the notes in this volume were handwritten and their content varies greatly--some reflect original work or work for a specific project, while others are mere clarifications of mathematical calculations or design specifications. As the authors converted the notes to electronic form, some were superficially edited and corrected, while others were extensively re-written to reflect current knowledge and notation. The notes are organized under five categories which reflect their primary content: Beam Position Monitors, (bpm), Current Sheet Electron Magnets (csem), Magnet Theory, (thry), Undulators and Wigglers (u-w), and Miscellaneous (misc). Within the category, they are presented chronologically starting from the most recent note and working backwards in time. DOE

SELF-CONSISTENT, 2D SIMULATIONS OF FILAMENT PROPAGATION IN PHOTOCONDUCTING SWITCHES
P. W. Rambo, W. S. Lawson, C. D. Capps (Boeing Defense and Space Group, Seattle, WA.), and R. A. Falk (Boeing Defense and Space Group, Seattle, WA.) Sep. 1994 10 p Presented at the SPIE Annual Conference of the Optical Society of America and Exhibit, Boston, MA, 30 Oct. - 4 Nov. 1994
(Contract W-7405-eng-48)
(DE95-010794; UCRL-JC-116955; CONF-941006-5) Avail: CASI HC A02/MF A01

The authors present simulations of time-dependent filament propagation in laser-triggered GaAs photoswitches. Unlike previous modeling, the calculations are self-consistent in 2-D axisymmetric (r-z) geometry. Realistic electron and hole mobilities as well as field dependent impact ionization are included. The authors report filament propagation with speeds U(sub f) approx. 10(exp 8)--10(exp 9) cm/s, much larger than the saturated carrier drift velocity, u(sup sat) approx. 10(exp 7) cm/s. The self-consistently determined filament radius and carrier number density are typically R(sub f) approx. 20--60 micro m and n(sub f) approx. 10(exp 17)--10(exp 18) cm(sup -3) respectively. Results are presented for filament propagation in systems with both uniform and nonuniform profiles of background carrier density and electric field. DOE

HTS JOSEPHSON TECHNOLOGY ON SILICON WITH APPLICATION TO HIGH SPEED DIGITAL MICROELECTRONICS Monthly Progress Report, 30 Oct. - 28 Nov. 1994
Peter Rosenthal 28 Nov. 1994 3 p

(Contract N00014-94-C-0261)
(AD-A288627) Avail: CASI HC A01/MF A01

We have identified parasitic inductance as a critical parameter governing the margins and performance of HTS RSFQ devices. Thermal expansion mismatch induced stress limits the overall thickness of HTS films on silicon substrates to under 70 nm. Because this thickness is less than the london penetration depth, typically 150 nm - 400 nm, we expect a substantial kinetic inductance to be associated with wiring and transmission lines. The kinetic inductance associated with the Josephson junctions themselves is still poorly understood. Because of the importance of inductance to overall circuit performance, we have fabricated and measured (Task 3) some dc SQUID's and RSFQ flip flops incorporating SQUID's. The estimated sheet parasitic kinetic inductance is given by the formula L sub sq = lambda sub L(2)/d, where lambda sub L is the London penetration depth, d is the film thickness (d much less than lambda sub L) and the current distribution is assumed to be uniform. The total loop inductance in a dc squid can be extracted from the magnitude of the magnetic field induced critical current modulation. We have performed measurements on a SQUID fabricated from a 25 nm thick film grown on an LaAlO3 substrate by the barium fluoride process. The inductance calculated over a wide temperature range are plotted in Figure 1. Similar results for a much smaller SQUID imbedded in an RSFQ flip flop are also shown in the figure. The temperature dependence to the sheet inductance is a signature of substantial kinetic inductance. Since kinetic inductance negatively impacts circuit performance, it is essential that careful quantitative account of all sources of inductance be included in circuit design efforts. DTIC

EFFECTIVE BANDWIDTH TECHNIQUES IN BUFFERLESS AND BUFFERED ATM MULTIPLEXERS
B. G. Kim and I. G. Niemegeers Oct. 1994 16 p
(PB95-207072; Memo-INF-94-47) Copyright Avail: CASI HC A03/MF A01

In order to aid the connection admission control, it is necessary to estimate the bandwidth required for a connection. The effective bandwidth techniques derives the estimated bandwidth for a source solely on the basis of the traffic characteristics of the source. Since it is not affected by the status of resource availability and the characteristics if other connections sharing resources, it is computationally efficient. The effective bandwidth can be derived in a multiplexer without a buffer by using the large deviations theory. The one in a buffered multiplexer can be derived by considering an asymptotic behavior with a large buffer size. Usually, the dominant eigenvalue plays a major role in the asymptotic behavior. Several bandwidth estimation techniques are summarized and compared with the results from the effective bandwidth techniques. NTIS

THIN-FILM EDGE FIELD EMITTER DEVICE AND METHOD OF MANUFACTURE THEREFOR Patent
Henry F. Gray, inventor (to Navy) and David S. Hsu, inventor (to Navy) 17 Jan. 1995 16 p Filed 31 Mar. 1993
(AD-D017453; US-Patent-5,382,185; US-Patent-Appl-SN-040944) Avail: US Patent and Trademark Office

Thin-film edge field emitter devices are provided which are capable of low voltage operation. The method of manufacture of the devices takes advantage of chemical beams deposition and other thin-film fabrication techniques. Both gated and ungated devices are provided and all of the devices include a plurality of thin-films deposited on the side-wall of a non-flat substrate. The gated emitter devices include alternating conductive and electrically insulating layers, and upper parts of the latter are removed to expose the upper edges of the conductive layers, with a central one of these conductive layers comprising an emitter for emitting electrons. The emitter devices can be inexpensively produced with a high degree of precision and reproducibility without the need for expensive lithographic machines. The devices can be used in field emitter arrays employed as vacuum transistors, vacuum microelectronic analog and digital devices, and modulated or cold electron sources. DTIC

METHOD AND APPARATUS FOR A HIGH RESOLUTION, FLAT PANEL CATHODOLUMINESCENT DISPLAY DEVICE Patent
Henry F. Gray, inventor (to Navy) and Ronald R. Price, inventor (to Navy) 3 Jan. 1995 11 p Filed 29 May 1992
(AD-D017434; US-Patent-5,378,962; US-Patent-Appl-SN-889885; US-Patent-Class-313-495) Avail: US Patent and Trademark Office

A high resolution, cathodoluminescent display screen or device and a method of producing such a display device is disclosed. The display screen includes a plurality of channel structures having longitudinal ends, a transparent medium formed in a plane to which the channel structures are fixed with one longitudinal end thereof oriented toward the plane of the transparent medium, and a cathodoluminescent material deposited on the channel structures whereby incident electrons and light generated by the incident electrons are directed along the channel structures. Preferably, the display screen also includes a mechanism for removing built up charge from the display screen, such as conductive channel structures and/or a conductive transparent medium. The cathodoluminescent material can include phosphors, and for producing a color display, different materials producing different colors would be used. In one preferred embodiment, the channel structures are tubules. Alternately, the channel structures can be channel plates or other structures providing channeling structures. In the preferred embodiment, the transparent medium is glass. However, the transparent medium could be quartz or some other equivalent material. In order to provide a display device the display screen is then mated with an addressable electron source for generating electrons incident on the cathodoluminescent material of selected channel structures. Preferably, the electron source means includes a field emitter array with a reflecting surface. DTIC

METHOD AND APPARATUS FOR NON-DESTRUCTIVELY MEASURING LOCAL RESISTIVITY OF SEMICONDUCTORS Patent
D. K. Gaskill, inventor (to Navy), Nicholas Bottka, inventor (to Navy), and Alok K. Berry, inventor (to Navy) 3 Jan. 1995 14 p Filed 17 Jun. 1992
(AD-D017436; US-Patent-5,379,109; US-Patent-Appl-SN-899977; US-Patent-Class-356-445) Avail: US Patent and Trademark Office

An apparatus for non-destructively measuring resistivity of a semiconductor, such as InP, comprises light sources for illuminating a preselected portion of the semiconductor with first and second light beams, each of a preselected single wavelength, the first light beam operating to excite the semiconductor by photo injecting carriers, and the second light beam bombarding the local portion of the semiconductor with a preselected photon energy. The apparatus measures a fractional change in reflectance of the second light beam responsive to the first light beam, and records this fractional change in reflectance for various values of photon energy of the second light beam, to generate a photoreflectance line-shape. The photoreflectance line-shape is used to calculate a photoreflectance line-shape phase angle, which is used to determine the resistivity of the preselected portion of the semiconductor. DTIC

QUANTUM 1/f NOISE IN HIGH TECHNOLOGY APPLICATIONS INCLUDING ULTRASMALL STRUCTURES AND DEVICES Final Technical Report, 15 Jun. 1989 - 14 Feb. 1994
Peter H. Handel 14 May 1994 76 p
(Grant AF-AFOSR-0416-89)
(AD-A292812) Avail: CASI HC A05/MF A01

The present report brings a final answer to the question on the nature of fundamental 1/f noise and its ubiquity. A sufficient criterion for a 1/f spectrum in arbitrary chaotic nonlinear systems is derived for the first time. This criterion guarantees a 1/f spectrum for nonlinear systems which also satisfy a condition of mathematical homogeneity. Briefly stated, nonlinearity + homogeneity = 1/f noise. The criterion results because the 1/f spectrum reproduces itself in a self-convolution. Among the five examples to which the criterion is applied is also quantum electrodynamics (QED), resulting in quantum 1/f noise as a fundamental form of quantum chaos. Nonlinearity of the system of a charged particle and its field, plus the basic homogeneity of physical equations causes the criterion to predict the quantum 1/f effect. The simple universal quantum 1/f formula is applied to infrared detectors and yields quantum 1/f noise in the dark current, but not in the photogenerated current. The fractal dimension of quantum 1/f noise is determined on the basis of its quantum chaos definition and is obtained theoretically as a function of bandwidth in a simple model by applying the Grassberger-Procaccia-Takens algorithm to the quantum 1/f theory. The quantum 1/f effect is successfully applied to quartz resonators and bipolar junction transistors. Finally, the quantum 1/f mobility fluctuations are calculated in silicon and the coherent quantum 1/f effect is derived for the first time from a new QED propagator with branch-point singularity. This opens the way to better bridging the gap between coherent and conventional quantum 1/f noise in small and ultrasmall devices. DTIC

MAGNESIUM BATTERY DISPOSAL CHARACTERISTICS

Louis Soffer and Terrill Atwater Dec. 1994 10 p

(AD-A293053; CECOM-TR-94-7) Avail: CASI HC A02/MF A01

This study assesses the disposal characteristics of U.S. Army procured military magnesium batteries under current Resource Conservation and Recovery Act (RCRA) hazardous waste identification regulations administered by the U.S. Environmental Protection Agency. Magnesium batteries were tested at 100, 50, 10 and 0 percent remaining state of charge. Present findings indicate that magnesium batteries with less than 50 percent remaining charge do not exceed the federal regulatory limit of 5.0 mg/L for chromium. All other RCRA contaminates were below regulatory limits at all levels of remaining charge. Assay methods, findings, disposal requirements and design implications are discussed. DTIC

Malloy (New Mexico Univ., Albuquerque, NM.) 1994 9 p Presented at the International Reliability Physics Symposium, Las Vegas, NV, 3-6 Apr. 1995

(Contract DE-AC04-94AL-85000)

(DE95-008824; SAND-95-0504C; CONF-950432-2) Avail: CASI HC A02/MF A01

Short-wavelength, visible-light emitting optoelectronic devices are needed for a wide range of commercial applications, including high-density optical data storage, full-color displays, and underwater communications. In 1994, high-brightness blue LED's based on gallium nitride and related compounds (InGaN/AlGaN) were introduced by Nichia Chemical Industries. The Nichia diodes are 100 times brighter than the previously available SiC blue LED's. Group-3 nitrides combine a wide, direct bandgap with refractory properties and high physical strength. So far, no studies of degradation of GaN based LED's have been reported. The authors study, reported in this paper, focuses on the performance of GaN LED's under high electrical stress conditions. Their observations indicate that, in spite of a high defect density, which normally would have been fatal to other 3-5 devices, defects in group-3 nitrides are not mobile even under high electrical stress. Defect tubes, however, can offer a preferential path for contact metals to electromigrate towards the p-n junction, eventually resulting in a short. The proposed mechanism of GaN diode degradation raises concern for prospects of reliable lasers in the group-3 nitrides grown on sapphire. DOE

HIGH PERFORMANCE YBCO FILMS R/D Final Report, 25 Mar. 1991 - 31 Mar. 1995

Edgar J. Denlinger 31 Mar. 1995 16 p

(Contract N00014-91-C-0216; ARPA Order 8100)

(AD-A293045) Avail: CASI HC A03/MF A01

A suitable low loss, low dielectric constant substrate for HTS circuitry has been identified and shown to permit the deposition of high quality YBCO films that are comparable to that achieved with lanthanum aluminate substrates. The substrate is magnesium fluoride which has a dielectric constant of 5.3 and a loss tangent of 0.0001 at 77 K. The benefits of this technology are higher speed interconnects for multichip module (MCM) assemblies applied to digital processing, higher power handling at microwave frequencies applied to multiplexers and other passive components, and lower frequency dispersion and lower loss at millimeter wave frequencies applied to antenna feed networks, T/R modules, and delay lines. We have developed a novel fabrication technique for MCM structures that features an ultra-thin YBCO-covered magnesium fluoride substrate glass bonded to a metal handle, which provides excellent mechanical support and good heat sinking characteristics. For a sample demonstration of this technology, an MCM structure with a YBCO signal plane that is suitable for microwave/millimeter wave circuitry was fabricated and tested to have excellent electrical characteristics with a YBCO film surface resistance of 1 mohm. CONTACTLESS CHARACTERIZATION OF SEMICONDUCTORS USING LASER-INDUCED SURFACE PHOTO-CHARGE VOLTAGE MEASUREMENTS Final Report

A. Abbate, P. Rencibia, O. Ivanov, G. Masini, F. Palma, and P. Das Jan. 1995 16 p Presented at the 1st International Symposium on Semiconductor Processing and Characterization with Lasers, Stuttgard, Germany

(AD-A293618; ARCCB-TR-95004) Avail: CASI HC A03/MF A01

A new technique to evaluate the electrical properties of semiconductor wafers and devices using surface photo-charge voltage (SPCV) measurements is presented. SPCV measures the change in the surface electrical charge induced by a chopped laser light whose photon energy exceeds the band gap energy of the semiconductor sample. This charge is measured capacitatively, thus SPCV measurements do not require the fabrication of metal contacts. In photocharge voltage spectroscopy measurements, the SPCV is measured as a function of the energy of a subband gap monochromatic steady-state illumination, and its derivative spectrum is associated with the density of surface states. A qualitative analysis of the proposed measurement is presented along with experimental results performed on gallium arsenide samples passivated with a thin zinc selenide film of variable thickness. The proposed technique is completely contactless, and it can be used as an in-line nondestructive characterization of semiconductor wafers during the various stages of integrated circuits fabrication. OPERATIONAL CHARACTERISTICS OF A 200 C LC PARALLEL RESONANT CIRCUIT

Eric D. Baumann and Ahmad N. Hammoud Jun. 1995 6 p Presented at the 1995 Conference on Electrical Insulation and Dielectric Phenomena, Virginia Beach, VA, 22-25 Oct. 1995; sponsored by IEEE Dielectrics and Electrical Insulation Society

(Contract NAS3-27186; RTOP 233-01-0C)

(NASA-TM-106983; E-9752; NAS 1.15:106983) Avail: CASI HC A02/MF A01

Research efforts are currently underway at the NASA Lewis Research Center to design and demonstrate an inverter capable of operating with a baseplate temperature of 200 C. In support of this project, various electrical components including capacitors, inductors, transformers, cables, and semiconductor switches are being developed or evaluated for integration into the inverter. In this work, a parallel LC resonant circuit was constructed and evaluated under simultaneous electrical and thermal stressing. The tests were performed in the temperature range of 25 to 200 C with an applied voltage of up to 90 V, 20 kHz. The individual components were comprised of high temperature film capacitors and powder core inductors developed in-house. The circuit was characterized in terms of the component currents and case temperatures as well as frequency of resonance as a function of applied bias and temperature. The results obtained, which have indicated good functional stability up to 200 C, are presented and discussed. Author

DESIGN OF DIGITAL LOW-PASS FILTERS FOR TIME-DOMAIN RECURSIVE FILTERING OF IMPACT ACCELERATION SIGNALS Final Report

Nabih Alem and Matthew Perry Jan. 1995 42 p

(DA Proj. 3O1-62787-A8-78)

(AD-A293086; USAARL-95-13) Avail: CASI HC A03/MF A01

Simplified and portable computer programs are presented to design and implement recursive digital Butterworth filters. The design method described uses the bilinear transformation to convert the well established analog design to digital formulation. Fortran codes for the design and implementation of the filter are included. The resulting design is compared to another filter proposed in SAE J211 guideline for filtering impact acceleration signals. Although both design methods produced filters which are within corridors prescribed in the J211 guideline, the standard design produces a Butterworth-like response whereas the J211 design does not. Additionally, the standard design methods and the implementation algorithms allow the design of any even order filter which may be required for filtering other long duration signals. DTIC

MISSION CRITICAL FAILURE EFFECTS ANALYSIS USING QUANTITATIVE TECHNIQUES Final Report, Feb. 1993 - Feb. 1994

Mark Royale, Rahul Kapoor, and Nick Kanopoulos Dec. 1994 104 p

(Contract F30602-93-C-0009)

(AD-A293098; RL-TR-94-212) Avail: CASI HC A06/MF A02

This report addresses the problem of assessing the criticality of faults in a large digital system. In particular, it addresses simulation-based methods for determining the effectiveness of built-in-test. The approach is based on automated fault injection in a VHDL model of the system, and statistical analysis of the resulting behavior of the system. The behavioral entities of the VHDL model would correspond to Line Replaceable Units (LRU's) or Line Replaceable Modules (LRM's). This report provides the top level design requirements and rationale for the detailed design of this capability. DTIC

AN ACTIVE MAGNETIC BEARING WITH HIGH T(SUB c) SUPERCONDUCTING COILS AND FERROMAGNETIC CORES

G. V. Brown, E. DiRusso, and A. J. Provenza Jul. 1995 11 p Presented at the 1995 Cryogenic Engineering Conference, Columbus, OH, 16-20 Jul. 1995; sponsored by Centennial Conferences

(RTOP 505-63-5B)

(NASA-TM-106995; E-9772; NAS 1.15:106995) Avail: CASI HC A03/MF A01

A proof-of-feasibility demonstration showed that high-T(sub c) superconductor (HTS) coils can be used in a high-load, active magnetic bearing in LN2. A homopolar radial bearing with commercially wound HTS (Bi 2223) bias and control coils produced over 890 N (200 lb) radial load capacity (measured non-rotatings) and supported a shaft to 14,000 rpm. The goal was to show that HTS coils can operate stably with ferromagnetic cores in a feedback controlled system at a current density similar to that for Cu in LN2. The bias coil, wound with non-twisted, multifilament HTS conductor, dissipated negligible power for its direct current. The control coils, wound with monofilament HTS sheathed in Ag, dissipated negligible power for direct current. AC losses increased rapidly with frequency and quadratically with AC amplitude. Above about 2 Hz, the effective resistance of the control coils exceeds that of the silver which is in electrical parallel with the oxide superconductor. These results show that twisted multifilament conductor is not needed for stable levitation but may be desired to reduce control power for sizable dynamic loads. Author

A TIME STEPPING COUPLED FINITE ELEMENT-STATE SPACE MODELING ENVIRONMENT FOR SYNCHRONOUS MACHINE PERFORMANCE AND DESIGN ANALYSIS IN THE ABC FRAME OF REFERENCE Ph.D. Thesis

Fang Deng 1994 290 p

Avail: Univ. Microfilms Order No. DA9422824

This dissertation centers on the development of a modeling environment to predict the performance and operating characteristics of salient-pole synchronous generators. The model basically consists of an algorithm consisting of two sections, a time stepping two-dimensional (2D) magnetostatic field finite element (FE) computation algorithm coupled to a state-space (SS) time-domain model of the winding circuits. Hence the term time stepping Coupled Finite Element-State Space (CFE-SS) modeling environment is adopted for this approach. In the FE section, magnetic vector potential (MVP) based finite element (FE) formulations and computation of two-dimensional (2D) magnetostatic fields are used to get the magnetic field solutions throughout a machine's cross-section at a sequence (samplings) of rotor positions covering a complete (360 deg e) ac cycle. These field solutions yield the winding inductances by means of an energy and current perturbation method. The output of the FE section is the magnetic field solutions and the entire set of phase, field, damper, and sleeve winding inductance profiles versus rotor position, including all space harmonics due to rotor saliency, damper bar slotting, sleeve segmentation, stator slotting, and magnetic saturation. These inductance profiles are decomposed into their harmonic components by Fourier analysis. The magnetic field solutions and resulting winding inductances represent the key input data to the SS portion of the CFE-SS modeling environment. Laminated machine iron core loss calculations, which include the losses in the stator and rotor as well as pole face are subsequently performed using the magnetic field solution data. Conversely, the output of the SS portion is the entire set of phase, field, damper winding (circuit), and sleeve segment currents, which also include all the resulting time harmonics. These winding current results form in turn the key input data to the FE portion of the modeling environment which is iteratively used in obtaining inductance parameters prior to another round of SS computation of the steady-state current profiles. Again, the model is iterative in nature, in which the user continues cycling through the two sections, namely the FE

and SS sections of the CFE-SS modeling environment, until the desired degree of convergence is achieved. The CFE-SS approach uses only design data such as physical dimensions, magnetic circuit geometry, magnetic material characteristics, winding particulars and layouts, and hence does not depend on the existence of actual hardware. The modeling environment is totally within the ABC frame of reference, therefore no approximating assumptions such as sinusoidally distributed mmf's or current sheets were made. Dissert. Abstr.

THE POTENTIAL FOR MICROTECHNOLOGY APPLICATIONS IN ENERGY SYSTEMS: RESULTS OF AN EXPERTS WORKSHOP
Feb. 1995 50 p
(Contract DE-AC06-76RL-01830)
(DE95-009103; PNL-10478) Avail: CASI HC A03/MF A01

Microscale technologies, or microelectromechanical systems (MEMS), are currently under development in the United States and abroad. Examples include microsensors, microactuators (including micromotors), and microscale heat exchangers. Typically, microscale devices have features ranging in size from a few microns to several millimeters, with fabrication methods adapted from those developed for the semiconductor industry. Microtechnologies are already being commercialized; initial markets include the biomedical and transportation industries. Applications are being developed in other industries as well. Researchers at the Pacific Northwest Laboratory (PNL) hypothesize that a significant number of energy applications are possible. These applications range from environmental sensors that support enhanced control of building (or room) temperature and ventilation to microscale heat pumps and microscale heat engines that could collectively provide for kilowatt quantities of energy conversion. If efficient versions of these devices are developed, they could significantly advance the commercialization of distributed energy conversion systems, thereby reducing the energy losses associated with energy distribution. Based upon the potential for energy savings, the U.S. Department of Energy (DOE) Office of Building Technologies (OBT) has proposed a new initiative in energy systems miniaturization. The program would focus on the development of microtechnologies for the manufactured housing sector and would begin in either FY 1997 or FY 1998, ramping up to $5 million per year investment by FY 2001. AN EXPERIMENTAL SEARCH FOR HIGH ZT SEMICONDUCTORS: A SURVEY OF THE PREPARATION AND PROPERTIES OF SEVERAL ALLOY SYSTEMS
S. H. Han and B. A. Cook 1994 5 p Presented at the 13th International Conference on Thermoelectrics, Kansas City, MO, 30 Aug. - 1 Sep. 1994
(Contract W-7405-eng-82)
(DE95-010232; IS-M-810; CONF-940830-4) Avail: CASI HC A01/MF A01

A survey was conducted of several alloy systems identified as having certain properties thought to be desirable in high figure-of-merit thermoelectric materials. The systems examined include the cerium and lanthanum borocarbides, yttrium nitrides, osmium silicides, and titanium sulfides. Various approaches to the preparation of these alloy systems were explored including vapor transport, arc melting, and mechanical alloying. Among these systems, the borocarbides were found to exhibit p-type conductivity but generally suffered from relatively high carrier concentrations (on the order of 10(exp 21)/cu cm and low mobilities (less than or equal to 10 sq cm/V-s). Both carbon and sulfur dopants produced the highest figure of merit (0.13 x 10(exp -3)/deg C in the yttrium nitride system at room temperature. Excess silicon was observed to increase carrier concentration and Hall mobility in osmium disilicide while additions of chromium were observed to stabilize the OsSi2 crystal structure. Electrical power factors comparable to state of the art silicon-germanium alloys were achieved in titanium disulfide, however, the electrical transport properties were found to be critically dependent upon the amount of excess Ti in Ti(1+x)S2. STABILITY ANALYSIS OF THE TPX TOROIDAL FIELD COIL
R. L. Wong 13 Oct. 1994 6 p Presented at the Applied Superconductivity Conference, Boston, MA, 16-21 Oct. 1994
(Contract W-7405-eng-48)
(DE95-009666; UCRL-JC-116966; CONF-941013-33) Avail: CASI HC A02/MF A01

The energy stability margin of the TPX/TF conductor has been calculated as a response to heat pulses with short initial quench zones and with long initial quench zones. The short IQZ's approximate ramp-rate induced heating, and the long IQZ's approximate heating from a plasma disruption. These IQZ's are centered in the bore inner leg of the double pancake, where the operating field and temperature are maximum. Energy margin stability curves are plotted as a function of current. At the 33.5 kA design current, the minimum calculated stability margin with short IQZ's is 390 mJ/cc. The minimum calculated stability margin with long IQZ's is 205 mJ/cc. A comparison the stability margin with the available enthalpy (short IQZ's) and with the available internal energy (long IQZ's) shows that the conductor utilizes the available helium energy well. The energy margin stability curve is generally divided into two regions. The regions can be characterized on the basis of a decrease or an increase in heating after the initiating heat pulse during a marginal quench. The low current well-cooled region exists when the heating rate during the pulse is greater than the Joule heating after the pulse. Since the heating rate decreases, the energy margin is high. The high current ill-cooled region exists when the heating rate during the pulse is less than the Joule heating after the pulse. Since the heating rate increases, the energy margin is low. In the evaluation of a well-cooled or an ill-cooled condition, this Joule heating should be included in the strength of the initiating pulse. When this is done for the TPX/TF conductor, the limiting current approaches the critical current, explaining why the stability curves are entirely in the well-cooled region. The important result is that the conductor does not exhibit a large decrease in energy margin to an ill-cooled region until the current approaches the critical current. DOE

EFFECTS OF TEMPERATURE, FREQUENCY, FLUX DENSITY, AND EXCITATION WAVEFORM ON THE CORE LOSS AND DYNAMIC B-H LOOPS OF SUPERMALLOY
Gene E. Schwarze, William R. Wieserman (Pittsburgh Univ., Johnstown, PA.), and Janis M. Niedra (NYMA, Inc., Brook Park, OH.) Jul. 1995 8 p Presented at the 30th Intersocieyty Energy Conversion Engineering Conference, Orlando, FL, 31 Jul. - 4 Aug. 1995; sponsored by ASME, IEEE, AIChE, ANS, SAE, ACS, and AIAA
(Contract NAS3-27186; RTOP 233-01-0C)
(NASA-TM-106982; E-9751; NAS 1.15:106982; IECEC-95-329) Avail: CASI HC A02/MF A01

The availability of experimental data which characterize the performance of soft magnetic materials for the combined conditions of temperature and frequency over a wide flux density range for different types of excitation is almost nonexistent. An experimental investigation of an 80-20 Ni-Fe alloy (Supermalloy) was conducted over the temperature (T) range of 23 to 300 C, frequency (f) range of 1 to 50 kHz, and maximum flux densities (B(sub M)) from 0.1 T up to 0.7 T for both sine and square wave voltage excitation. The investigation focused on the effects of (B(sub M)), f, T, and excitation waveform on the specific core loss (SCL) and dynamic B-H loops. The results show that the ratio (R) of sine to square wave excitation specific core loss was always greater than unity for a given f and T and identical values of B(sub M). The values of R ranged from 1.07 to 1.34. The classical theory of core loss separation into a hysteresis and eddy current loss component was used to theoretically determine the lower and upper bounds on R, against which the experimental R-values were compared. The experimental R-values were also used to make a comparison of the core loss of a sine and square wave voltage driven transformer. Author

VOLTAGE CONTROLLED MESFET PULSE SHAPE GENERATOR
Scott C. Burkhart 26 Oct. 1994 7 p
(Contract W-7405-eng-48)
(DE95-011656; UCRL-ID-116054) Avail: CASI HC A02/MF A01

A programmable pulse shape generator capable of producing pulse shapes for Nova and Beamlet has been designed and simulated using the circuit code SPICE. The design utilizes power MESFETS, which are commonly used in microwave amplifiers. The pulse shape is varied by setting a bias voltage on each in a chain of MESFETS with a 200 ps temporal resolution. The electrical pulse then drives an integrated

electro-optic modulator similar to what is on Beamlet. Pulse shapes 22 and 25, used on Nova, have been generated by this design. There is no fundamental barrier to making such a pulse generator for use on the National Ignition Facility (NIF). In fact, the longer time scales on the NIF pulse will ease the high speed requirements of the pulse shape generator allowing the use of less expensive components. DOE

VISCOUS DIFFUSION OF VORTICITY IN UNSTEADY WALL LAYERS USING THE DIFFUSION VELOCITY CONCEPT
J. H. Strickland, S. N. Kempka, and W. P. Wolfe 1995 14 p Presented at the Application of Vortex Methods to Engineering Problems Forum, Albuquerque, NM, 22-24 Feb. 1995
(Contract DE-AC04-94AL-85000)
(DE95-008537; SAND-95-0278C; CONF-950283-2) Avail: CASI HC A03/MF A01

The primary purpose of this paper is to provide a careful evaluation of the diffusion velocity concept with regard to its ability to predict the diffusion of vorticity near a moving wall. A computer code BDIF has been written which simulates the evolution of the vorticity field near a wall of infinite length which is moving in an arbitrary fashion. The simulations generated by this code are found to give excellent results when compared to several exact solutions. We also outline a two-dimensional unsteady viscous boundary layer model which utilizes the diffusion velocity concept and is compatible with vortex methods. A primary goal of this boundary layer model is to minimize the number of vortices generated on the surface at each time step while achieving good resolution of the vorticity field near the wall. Preliminary results have been obtained for simulating a simple two-dimensional laminar boundary layer. DOE

ELECTROMAGNETICALLY ACTIVATED COMPLIANT WAVY-WALL Patent
Richard H. Nadolink, inventor (to Navy) 25 Oct. 1994 9 p Filed 27 Aug. 1993
(AD-D017340; US-Patent-5,359,574; US-Patent-Appl-SN-113378; US-Patent-Class-367-1) Avail: US Patent and Trademark Office

Electromagnets are disposed in an elastomeric coating affixed to a body exposed to a fluid. Controllable magnetic forces created by the electromagnets produce a wavy-wall configuration in the surface of the coating which may be static, dynamic, or static in part and dynamic in part, and which interfaces with the fluid to controllably alter noise, turbulence and drag characteristics of the body mechanically. Electrodes may be fixed on the surface of the coating to produce electric force fields for interacting with the magnetic fields and the wavy-wall, to produce magnetohydrodynamically generated Lorentz forces which controllably further alter noise, turbulence and drag characteristics of the body. SMALL SCALE TURBULENCE IN A PLANE MIXING LAYER Ph.D. Thesis
Judith Kathleen Foss 1994
Avail: Issuing Activity (Univ. of Southern California, Doheny Library, Micrographics Dept., Los Angeles, CA 90089-0182)

Two measures of small scale turbulence, viscous dissipation and a direct count of the random fine eddies which dissipate energy, were correlated to the large scale coherent motions in a plane mixing layer. Experiments were conducted in a low speed wind tunnel at moderate Reynolds number with laminar boundary layers separating from both the high and low speed sides. Extensive x- and parallel-wire measurements yielded three-component velocity data taken point by point in a plane normal to the freestream. The location of the large scale coherent motions was determined by spatially differentiating the long-time averages of these data. The primary spanwise vortex was identified from Delta U/Delta y while the secondary streamwise ribs were obtained from Delta V/Delta z, where Delta y and Delta z represent the spacing between data points in the cross-stream and spanwise directions, respectively. It will be demonstrated how Delta U/Delta z identifies the rib locations, as well. The data, moreover, were taken so that the fine-scale eddies, those whose length scale corresponds exactly to the peak in the 3-D dissipation spectrum, were resolved both spatially and temporally. These 'dissipative' eddies were identified by a novel technique, the peak-valley-counting (PVC) method. Several of the viscous dissipation terms were also calculated. The fine-scale eddy population distributions and the measures of viscous dissipation correlated extremely well. Indeed, the 'dissipative' eddies dissipate the energy, and the PVC method identifies them. Both sets of distributions peak in the core of the spanwise vortex, and are independent of the streamwise ribs at this downstream location. Dissert. Abstr.

(DE95-008715; SAND-94-1735C; CONF-950283-1) Avail: CASI HC A03/MF A01

Velocity boundary conditions for the vorticity form of the incompressible, viscous fluid momentum equations are presented. Vorticity is created on boundaries to simultaneously satisfy the tangential and normal components of the velocity boundary condition. The newly created vorticity is specified by a kinematical formulation which is a generalization of Helmholtz decomposition of a vector field. Related forms of the decomposition were developed by Bykhovskiy and Smirnov in 1983, and Wu and Thompson in 1973. Though it has not been generally recognized as such, these formulations resolve the over-specification issues associated with determining

a velocity field from velocity boundary conditions and a vorticity field. The generalized decomposition has not been widely used, however, apparently due to a general lack of a useful physical interpretation. An analysis is presented which shows that the generalized decomposition has a relatively simple physical interpretation which facilitates its numerical implementation. The implementation of the generalized decomposition for the normal and tangential velocity boundary conditions is discussed in detail. As an example of the use of this boundary condition, the flow in a lid-driven cavity is simulated. The solution technique is based on a Lagrangian transport algorithm in the hydrocode ALEGRE. ALEGRE's Lagrangian transport algorithm has been modified to solve the vorticity transport equation, thus providing a new, accurate method to simulate incompressible flows. This numerical implementation and the new boundary condition formulation allow vorticity-based formulations to be used in a wider range of engineering problems. DOE

THE EFFECT OF ADDING ROUGHNESS AND THICKNESS TO A TRANSONIC AXIAL COMPRESSOR ROTOR

Kenneth L. Suder, Rodrick V. Chima, Anthony J. Strazisar, and William B. Roberts (Flow Application Research, Fremont, CA.) Jun. 1995 22 p Presented at the 39th International Gas Turbine and Aeroengine Congress and Exposition, The Hague, Neatherlands, 13-16 Jun. 1994; sponsored by ASME

(RTOP 505-62-52)

(NASA-TM-106958; E-9709; NAS 1.15:106958) Avail: CASI HC A03/MF A01

The performance deterioration of a high speed axial compressor rotor due to surface roughness and airfoil thickness variations is reported. A 0.025 mm (0.001 in.) thick rough coating with a surface finish of 2.54-3.18 RMS microns (100-125 RMS microinches) is applied to the pressure and suction surface of the rotor blades. Coating both surfaces increases the leading edge thickness by 10% at the hub and 20% at the tip. Application of this coating results in a loss in efficiency of 6 points and a 9% reduction in the pressure ratio across the rotor at an operating condition near the design point. To separate the effect of thickness and roughness, a smooth coating of equal thickness is also applied to the blade. The smooth coating surface finish is 0.254-0.508 RMS microns (10-20 RMS microinches), compared to the bare metal blade surface finish of 0.508 RMS microns (20 RMS microinches). The smooth coating results in approximately half of the performance deterioration found from the rough coating. Both coatings are then applied to different portions of the blade surface to determine which portions of the airfoil are most sensitive to thickness/roughness variations. Aerodynamic performance measurements are presented for a number of coating configurations at 60%, 80%, and 100% of design speed. The results indicate that thickness/roughness over the first 10% of blade chord accounts for virtually all of the observed performance degradation for the smooth coating, compared to about 70% of the observed performance degradation for the rough coating. The performance deterioration is investigated in more detail at design speed using laser anemometer measurements as well as predictions generated by a quasi-3D Navier-Stokes flow solver which includes a surface roughness model. Measurements and analysis are performed on the baseline blade and the full-coverage smooth and rough coatings. The results indicate that coating the blade causes a thickening of the blade boundary layers. The interaction between the rotor passage shock and the thickened suction surface boundary layer then results in an increase in blockage which reduces the diffusion level in the rear half of the blade passage, thus reducing the aerodynamic performance of the rotor. AN EXPERIMENTAL STUDY OF PLANAR HETEROGENEOUS SUPERSONIC CONFINED JETS Ph.D. Thesis

Frederick J. Tanis, Jr. Dec. 1994 184 p

(AD-A290859; AFIT/DS/AA/94-6) Avail: CASI HC A09/MF A02

The effects of varying the exit pressure of a supersonic helium jet exhausting coaxially with two parallel supersonic air streams into a constant area duct were investigated. The method used to evaluate the mass entrainment rate was to measure helium molar concentration profiles and mass flux across the duct using a binary gas probe then calculate the mass entrainment into the helium jet. In order to conduct this study a novel binary gas probe was developed which allowed helium concentration and mass flux data to be obtained during continuous traverses across the supersonic flowfield. High exit pressure ratio (EPR) led to improved overall mixing compared to the baseline case with an EPR near unity. The high EPR caused low mass entrainment along the jet shear layers due to high convective Mach numbers and velocity ratios, but the high EPR caused oblique shocks to form which reflected off the duct walls and intersected with the helium jet several times causing significant mass entrainment due to numerous shock-shear layer interactions (SSLI's). A correlation between the vorticity generated during a SSLI and the mass entrainment into the jet was developed. DTIC

METHOD AND SYSTEM FOR REDUCING DRAG ON A BODY MOVING THROUGH A FLUID MEDIUM Patent

Richard A. Katz, inventor (to Navy) 15 Nov. 1994 18 p Filed 2 Sep. 1993

(AD-D017336; US-Patent-5,365,490; US-Patent-Appl-SN-117512; US-Patent-Class-367-1) Avail: US Patent and Trademark Office

A method of detecting the onset of turbulence in connection with a body moving through a fluid medium and of reducing body drag and as well reducing the amount of drag noise radiated from the body. First, the body is supplied with sensors each for generating a signal suitable for measuring amplitude of pressures fluctuations of the of this medium proximate a region of said sidewall of the body in at least a region of the body in which turbulence is expected to occur. During a reference stage during which the body moves through the fluid medium when it is known that turbulence is occurring around at least a portion of said body, the sensors each generate reference temporal pressure data representing fluctuations in pressure of the fluid medium around said body. In response to reference temporal pressure data generated by sensors in a turbulence zone at which turbulence is occurring and sensors in a transition zone between the turbulence zone and a laminar flow zone, method-of-delay phase portraits are generated for a progression of selected delay intervals. NUMERICAL SIMULATION OF FLOW IN A WHIRLING ANNULAR SEAL AND COMPARISON WITH EXPERIMENTS

M. M. Athavale (CFD Research Corp., Huntsville, AL.), R. C. Hendricks, and B. M. Steinetz Jun. 1995 22 p Presented at the 31st Joint Portpulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; sponsored by AIAA, ASME, SAE, and ASEE Original contains color illustrations

(Contract NAS3-25644; RTOP 242-70-02)

(NASA-TM-106961; NAS 1.15:106961) Avail: CASI HC A03/MF A01; 2 functional color pages

The turbulent flow field in a simulated annular seal with a large clearance/radius ratio (0.015) and a whirling rotor was simulated using an advanced 3D CFD code SCISEAL. A circular whirl orbit with synchronous whirl was imposed on the rotor center. The flow field was rendered quasi-steady by making a transformation to a totaling frame. Standard k-epsilon model with wall functions was used to treat the turbulence. Experimentally measured values of flow parameters were used to specify the seal inlet and exit boundary conditions. The computed flow-field in terms of the velocity and pressure is compared with the experimental measurements inside the seal. The agreement between the numerical results

and experimental data with correction is fair to good. The capability of current advanced CFD methodology to analyze this complex flow field is demonstrated. The methodology can also be extended to other whirl frequencies. Half- (or sub-) synchronous (fluid film unstable motion) and synchronous (rotor centrifugal force unbalance) whirls are the most unstable whirl modes in turbomachinery seals, and the flow code capability of simulating the flows in steady as well as whirling seals will prove to be extremely useful in the design, analyses, and performance predictions of annular as well as other types of seals. SINGULAR EIGENFUNCTIONS FOR SHEARING FLUIDS I
N. J. Balmforth and P. J. Morrison Feb. 1995 79 p
(Contract DE-FG05-80ET-53088)
(DE95-008952; DOE/ET-53088/692; IFSR-692) Avail: CASI HC A05/MF A01

The authors construct singular eigenfunctions corresponding to the continuous spectrum of eigenvalues for shear flow in a channel. These modes are irregular as a result of a singularity in the eigenvalue problem at the critical layer of each mode. They consider flows with monotonic shear, so there is only a single critical layer for each mode. They then solve the initial-value problem to establish that these continuum modes, together with any discrete, growing/decaying pairs of modes, comprise a complete basis. They also view the problem within the framework of Hamiltonian theory. In that context, the singular solutions can be viewed as the kernel of an integral, canonical transformation that allows us to write the fluid system, an infinite-dimensional Hamiltonian system, in action-angle form. This yields an expression for the energy in terms of the continuum modes and provides a means for attaching a characteristic signature (sign) to the energy associate with each eigenfunction. They follow on to consider shear-flow stability within the Hamiltonian framework. Next, the authors show the equivalence of integral superpositions of the singular eigenfunctions with the solution derived with Laplace transform techniques. In the long-time limit, such superpositions have decaying integral averages across the channel, revealing phase mixing or continuum damping. Under some conditions, this decay is exponential and is then the fluid analogue of Landau damping. Finally, the authors discuss the energetics of continuum damping. DOE

EXISTENCE OF SOLUTIONS IN PLANE QUASISTATIONARY STOKES FLOW DRIVEN BY SURFACE TENSION
G. Prokert Nov. 1994 26 p
(PB95-197935; RANA-94-23) Avail: CASI HC A03/MF A01

Recently, the free boundary problem of quasistationary Stokes flow of a mass of viscous liquid under the action of surface tension forces has been considered by R.W. Hopper, L.K. Antanovskii, and others. The solution of the Stokes equations is represented by analytic functions, and a time dependent conformal mapping onto the flow domain is applied for the transformation of the problem to the unit disk. Two coupled Hilbert problems have to be solved there which leads to a Fredholm boundary integral equation. The solution of this equation determines the time evolution of the conformal mapping. The question of existence of a solution to this evolution problem for arbitrary (smooth) initial data has not yet been answered completely. In this paper, local existence in time is proved using a theorem of Ovsiannikov on Cauchy problems in an appropriate scale of Banach spaces. The necessary estimates are obtained in a way that is oriented at the a priori estimates for the solution given by Antanovskii. In the case of small deviations from the stationary solution represented by a circle, these a priori estimates together with the local results are used to prove even global existence of the solution in time. NUMERICAL COMPUTATION OF ONE-DIMENSIONAL DETONATION WAVES
A. C. Berkenbosch, E. F. Kaasschieter, and J. H. M. tenThijeBoonkkamp Oct. 1994 29 p
(PB95-197950; RANA-94-21) Avail: CASI HC A03/MF A01

In this paper we consider the numerical computation of one-dimensional detonation waves. Detonation waves are travelling wave solutions of the reactive Euler equations. An essential numerical difficulty in the numerical computation of detonation waves is the occurrence of completely wrong wave speeds, corresponding with non-physical solutions of the reactive Euler equations. The numerical propagation speed is strongly influenced by the choice of the ignition temperature. In this paper it is proved that non-physical solutions are always weak detonation waves. Furthermore, we present theoretical insights assessing why a correct ignition temperature will exclude non-physical weak detonation waves, just like the entropy condition excludes non-physical expansion shocks in the non-reacting case. This is illustrated by numerical computations quite well. NTIS

SIMULATION OF VISCOUS SINTERING
G. A. L. vandeVorst and R. M. M. Mattheij Oct. 1994 50 p Sponsored by the Technology Foundation
(PB95-197109; RANA-94-19) Avail: CASI HC A03/MF A01

The objective of this research is to develop reliable numerical methods to predict the deformation of an incompressible Newtonian viscous fluid region (Stokes Flow) driven by surface tension. In particular this mathematical model describes the physical processes that appear when a compact of glassy particles is heated to such a high temperature that the glass becomes a viscous creeping fluid. As a result, the particles are joining together so that the cohesion of the compact is increasing with time. This phenomenon is usually called viscous sintering and, e.g., appears in the production of high-quality glasses. From the methods developed, theoretical insights can be obtained about the densification kinetics of such a compact. Therefore, a numerical simulation program is developed that calculates the deformation of a representative two-dimensional or an axisymmetric unit cell of the compact. A Boundary Element Method is applied to solve the involved integral equations of Stokes flow and the time integration is carried out by a variable step, variable order Backward Differences Formulae method. A TURBULENCE MODEL FOR STEADY AND UNSTEADY BOUNDARY LAYERS IN STRONG PRESSURE GRADIENTS Ph.D. Thesis
Evangelos Hytopoulos 1994 234 p
Avail: Univ. Microfilms Order No. DA9422527

A new turbulence model designed for two-dimensional, steady and unsteady boundary layers in strong adverse pressure gradients is described. The model is developed in a rational way based on an understanding of the flow physics obtained from recent experimental observations. The turbulent shear stress is given by a mixing length model, but the variation of the mixing length in the outer region is not constant; it varies according to an integral form of the turbulence kinetic-energy equation. This approach allows for the history effects of the turbulence to be taken into account in an approximate but rational way. The form of the near-wall mixing length model is derived based on the rigorous distribution of the shear stress near the wall, and it takes into account the pressure and convection terms which become important in strong adverse pressure gradients. Since the significance of the normal stresses in turbulent kinetic-energy production is increasing as separation is approached, a model accounting for this contribution is incorporated. The model is calibrated using available experimental data. These data also indicate a change in turbulence structure near and through separation. Such a change can be significant and is accounted for here using an empirical function. The complete model was tested against steady and unsteady, two-dimensional experimental cases with adverse pressure gradient up to separation. Improved predictions compared to those obtained with other turbulence models were demonstrated. The general and rational approach that led to the derivation of the model allows the straightforward extension of the model in the region of separation. The further extension to steady and unsteady, three-dimensional cases is indicated. Dissert. Abstr.

NAVIER-STOKES FLOW FIELD ANALYSIS OF COMPRESSIBLE FLOW IN A HIGH PRESSURE SAFETY RELIEF VALVE
Bruce Vu, Ten-See Wang, Ming-Hsin Shih (Mississippi State Univ., Mississippi State, MS.), and Bharat Soni (Mississippi State Univ., Mississippi State, MS.) [1993] 9 p
(NASA-TM-110640; NAS 1.15:110640) Avail: CASI HC A02/MF A01

The objective of this study is to investigate the complex three-dimensional flowfield of an oxygen safety pressure relieve valve during an incident, with a computational fluid dynamic (CFD) analysis. Specifically, the analysis will provide a flow pattern that would lead to the expansion of the eventual erosion pattern of the hardware, so as to combine it with other findings to piece together a most likely scenario for the investigation. The CFD model is a pressure based solver. An adaptive upwind difference scheme is employed for the spatial discretization, and a predictor, multiple corrector method is used for the velocity-pressure coupling. The computational result indicated vortices formation near the opening of the valve which matched the erosion pattern of the damaged hardware. Author

NEARLY STEADY FLOWS IN GONG PROTOTYPE DATA

David H. Hathaway 1993 4 p Sponsored by the National Science Foundation

(RTOP 170-38-53-56)

(NASA-CR-198935; NAS 1.26:198935) Avail: CASI HC A01/MF A01

Doppler velocity images obtained with the GONG prototype instrument were analyzed to measure the nearly steady photospheric flows. The data consists of 88 images each of velocity, intensity, and modulation obtained at 20:00 UT on 88 days from July 1992 to February 1994. Each velocity image was temporally filtered to remove the p-mode oscillations, masked to exclude active regions, and then analyzed using spherical harmonics and orthogonal functions as described by Hathaway (1992). The spectral coefficients show very consistent results for the entire time interval with some evidence of year-to-year variations. The rotation profile agrees well with previous results and exhibits a north-south asymmetry that reverses sign during the 20 month interval. The residual rotation velocities exhibit structures with amplitudes of approximately 5 m/s that may be related to torsional oscillations. The meridional circulation is directed from the equator toward the poles with a peak velocity in the photosphere of approximately 50 m/s. The higher order components are very weak but indicate a divergent flow from the mid-latitudes (opposite that found for the June 1989 data). The convective limb shift is well fit by a 3rd order polynomial. The convection spectrum has a prominent peak at spherical harmonic degrees of l approximately 150 with very little signal in the low degree modes. Analysis of this signal shows that there is no evidence for giant cell convection at the level of approximately 10 m/s for all modes up to l = 32. Author

SIMULTANEOUS HEAT AND MASS TRANSFER IN A HORIZONTAL TUBE ABSORBER: NUMERICAL TOOLS FOR PRESENT AND FUTURE ABSORBER DESIGNS Ph.D. Thesis

Reinder Hette Wassenaar 7 Nov. 1994 245 p

(PB95-196978; ISBN-90-370-0109-3) Copyright Avail: CASI HC A11/MF A03

Absorption cycles like the absorption heat pump or the absorption heat transformer can contribute to savings on one of the earth's resources, energy. Because of the high initial expenses, application of an conventional absorption apparatus is only economical in the MW range at today's prices. In this project numerical tools were developed for the design of heat and mass exchangers with a better price-performance ratio, that open a wider field of application for absorption cycles. The tools are mathematical formulations of the conservation of energy and mass for absorption in a falling film flow along a cooled wall. The resulting set of partial differential equations with appropriate boundary conditions is made dimensionless to make them applicable to any mixture or geometry and to summarize the model parameters in a few dimensionless groups. The numerical tools developed give, in contrast to the existing finite difference descriptions, accurate outcomes at very low computational costs and apply also on a flow field of arbitrary geometry. THREE-DIMENSIONAL (3D) LARGE FLUID FLOW COMPUTATIONS FOR US ARMY APPLICATIONS ON KSR-1, CM-200, CM-5, AND CRAY C-90 Final Report, Jul. 1992 - Jul. 1994

Nisheeth Patel, Harris Edge, and Jerry Clarke Feb. 1995 31 p

(AD-A293125; ARL-TR-712) Avail: CASI HC A03/MF A01

The thrust of this research is to investigate the use of emerging massively parallel computer architectures for production type fluid flow applications. Typical flow computations in a ballistic simulation have reached a stage where a grid set involving a couple of million points are needed for adequate understanding of the flow behavior and computing the resulting forces acting on a projectile with a complex geometrical shape. For acceptable turnaround time, the simulation requires a system with large memory and high performance. Because of the hardware scalability and availability of large in-core memory, the emerging massively parallel processors (MPP) architectures such as Connection Machine's CM-5 and Kendall Square Research KSR-1 have become attractive for ballistic computations. Thus, this research is focused on implementation of complex real-world applications (not simple scaled down problems) on MPP's with the goal of sustainable performance. Because performance measurements obtained using the kernel of the full application and/or scaled down application size or 2-D cases could lead to considerably higher performance estimates, these factors are discussed in light of results from full 3-D applications obtained on MPP's. WAVE PROPAGATION IN A FLUID-LOADED HOMOGENEOUS, TRANSVERSELY ISOTROPIC, ELASTIC CYLINDER OF ARBITRARY THICKNESS Ph.D. Thesis

Marilyn J. Berliner 15 Mar. 1995 140 p

(AD-A292728; NUWC-NL-TR-10845) Avail: CASI HC A07/MF A02

The problem of wave propagation in an infinite, fluid-loaded, homogeneous, transversely isotropic cylinder is studied within the framework of the linearized, three-dimensional theory of elasticity. The equations of motion of the cylinder are formulated using the constitutive equations of a transversely isotropic material with a preferred material direction collinear with the longitudinal axis of the cylinder. The equations of motion of the internal and external fluids are formulated using the constitutive equations of an inviscid fluid. Displacement potentials are used to solve the equations of motion of the cylinder and the fluids. The frequency equation of the coupled system, consisting of the cylinder and the internal and external fluids, is developed under the assumption of perfect-slip boundary conditions at the fluid-solid interfaces. This frequency equation is general in axial wavenumber k, circumferential wavenumber n, cylinder wall thickness h, and radial frequency. Cut-off frequencies and frequency spectra are computed for the n=1 modes in hollow cylinders, hypothetical fluid columns, fluid-filled cylinders, and cylinders that are fluid filled and immersed in fluid. Numerical results are obtained for two isotropic cylinders (composed of steel and soft (linear) and for a highly anisotropic, fiber-reinforced cylinder. DTIC

DYNAMICAL SYSTEMS AS MODELS FOR FLOW-INDUCED VIBRATIONS

A. H. P. vanderBurgh 1994 34 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality

(PB95-206991) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

In this paper a number of oscillators with two degrees of freedom is considered. Attention is paid to the case in which only one degree of freedom interacts with a flowing medium. For the modeling of the flow-induced vibrations use is made of a quasi-steady theory. Model equations systems of non-linearly coupled harmonic oscillators are obtained. The analysis of these equations is restricted to special periodic and quasi-periodic solutions. The physical interpretation may be of relevance for the understanding of a number of technical problems. NTIS

ACCELERATION POTENTIAL MODELS PREDICHAT/PREDICDYN APPLIED FOR CALCULATION OF AXISYMMETRIC DYNAMIC INFLOW CASES

G. J. W. vanBussel Dec. 1993 32 p

(PB95-207015; IW-93071R) Avail: CASI HC A03/MF A01

Under the assumption of incompressible, inviscid and irrotational flow, it can be shown that the pressure perturbation in the complete flow field is given by a Laplace equation and acts as an acceleration potential function. The rotor blades are represented in the model as discrete surfaces on which a pressure discontinuity is present. The model implies the presence

of spanwise and chordwise pressure distributions, which are composed of analytical asymptotic solutions for the Laplace equation. This model is implemented in the PREDICHAT and PREDICDYN computer code series, for steady and axisymmetric dynamic inflow cases respectively. Dynamic inflow concerns with large scale unsteady rotor aerodynamics, such as coherent wind gusts, collective blade pitch and rotor speed variations. The basic equations implemented in the codes are presented, as well as some results from uniform flow, blade pitching and a safety stop. Comparisons with other calculations and with measurements are presented and show a good agreement. NTIS

10 kW HEAT PIPE-HEAT SINK DEVELOPMENT

Chengti Qiu and Deren Xie 27 Mar. 1995 21 p Transl. into ENGLISH from Nanjing Gongxueyuan Xuebao, China, v. 16, no. 4, 1986 p 76-85 (AD-A293167; NAIC-ID(RS)T-0495-94) Avail: CASI HC A03/MF A01

A design of heat pipe with heat sink for cooling 10 kW klystron is presented. The radial heat pipe with heat sink is adopted and the later is optimized by computer for its minimum weight. In order to find its performance and life, the life testing is made and lasted for 1154 hours under the dissipated 5kW condition in addition to the traditional performance testing. The results obtained show that this heat pipe with heat sink is reliable, and with which the calculation results are consistent. DTIC

SURVEY OF RECENT Al2O3 DROPLET SIZE DATA IN SOLID ROCKET CHAMBERS, NOZZLES, AND PLUMES c20

Mark Salita *In* JHU, The 21st JANNAF Exhaust Plume Technology Meeting, Volume 1 Oct. 1994 p 1-17 (For primary document see N95-30986 11-34)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The size distribution of Al2O3 droplets in a solid propellant rocket is very different in the chamber, nozzle, and plume, primarily due to breakup and collision/coalescence in the nozzle. This paper attempts to summarize, evaluate, and relate the results of 19 recent experimental and analytical studies of droplet size in order to construct a unified model of droplet size evolution from the chamber through the nozzle and into the plume. It is believed that the distribution of droplet mass in the chamber is bimodal lognormal, with 1 micrometer smoke comprising about 80 percent of the mass and 50-100 micrometer caps comprising the remaining 20 percent. During passage through the nozzle, the caps shatter to product droplets whose diameters are about 10 percent of the caps but still 10 times those of smoke, while all but 1-2 percent of the smoke mass collides and coalesces with the shatter products to generate an essentially monomodal mass distribution at the nozzle exit whose D(sub 43) agrees with Hermsen's correlation and whose standard deviation sigma approximately equals 0.13 is smaller than both the chamber smoke (sigma approximately equals 0.40) or caps (sigma approximately equals 0.20). THE Al AND A(LC)L2O3 DROPLET CLOUD IN SOLID ROCKET MOTORS c20

Ed W. Price and R. K. Sigman *In* JHU, The 21st JANNAF Exhaust Plume Technology Meeting, Volume 1 Oct. 1994 p 19-28 (For primary document see N95-30986 11-34)

(Contract N00014-89-J-1293)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A discussion is presented of the current state of understanding and prediction of size and spatial distribution of aluminum and Al2O3 droplets in a motor. It is noted that available theory and experimental results are inadequate for prediction of two phase flow effects (e.g., slag formation, damping of oscillations), especially with propellants other than those based on AP and hydrocarbon binder. Potentially important phenomena that have received almost no attention include fragmentation of Al droplets near burnout, and growth of larger oxide droplets by accretion of fine 'smoke' droplets. SHUTTLE REDESIGNED SOLID ROCKET MOTOR ALUMINUM OXIDE INVESTIGATIONS c20

Fred S. Blomshield, Karl J. Kraeutle, and Richard A. Stalnaker *In* JHU, The 21st JANNAF Exhaust Plume Technology Meeting, Volume 1 Oct. 1994 p 29-39 Sponsored by NASA. Marshall Space Flight Center (For primary document see N95-30986 11-34)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

During the launch of STS-54, a 15 psi pressure blip was observed in the ballistic pressure trace of one of the two Space Shuttle Redesigned Solid Rocket Motors (RSRM). One possible scenario for the observed pressure increase deals with aluminum oxide slag formation in the RSRM. The purpose of this investigation was to examine changes which may have occurred in the aluminum oxide formation in shuttle solid propellant due to changes in the ammonium perchlorate. Aluminum oxide formation from three propellants, all having the same formulation, but containing ammonium perchlorate from different manufacturers, will be compared. Three methods have been used to look for possible differences among the propellants. The first method was to examine window bomb movies of the propellants burning at 100, 300 and 600 psia. The motor operating pressure during the pressure blip was around 600 psia. The second method used small samples of propellant which were fired in a combustion bomb which quenched the burning aluminum particles soon after they left the propellant surface. The bomb was fired in both argon and Nitrogen atmospheres at various pressures. Products from this device were examined by optical microscopy. The third method used larger propellant samples fired into a particle collection device which allowed the aluminum to react and combust more completely. This device was pressurized with Nitrogen to motor operating pressures. The collected products were subdivided into size fractions by screening and sedimentation and analyzed optically with an optical microscope. The results from all three methods indicate very small changes in the size distribution of combustion products. Author

BURN TIME MEASUREMENTS OF SINGLE ALUMINUM PARTICLES IN STEAM AND CARBON DIOXIDE MIXTURES c25

Shane E. Olsen and Merrill W. Beckstead *In* JHU, The 21st JANNAF Exhaust Plume Technology Meeting, Volume 1 Oct. 1994 p 41-58 (For primary document see N95-30986 11-34)

(Grant AF-AFOSR-0152-91)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

In this study, single aluminum particles (40 to 80 micrometers) were burned in H2O/CO2 mixtures. Burn times were measured electronically using a PMT. In addition, the effect of oxidizer composition was determined. Burn times were also measured for single particles, quenched at various stages of combustion. SEM micrographs of quenched specimens were obtained. The results were used in determining particle burn times. Study of quenched particles revealed the formation of large hollow aluminum oxide spheres nearly the size of the original aluminum particle. These spheres have been reported by other investigators at both atmospheric and high pressure conditions. It was found that burn time measurements

are very sensitive to the method of analysis used. Using the results of an aluminum combustion model by Brooks (1993), effective oxygen concentrations were calculated for this work and other data. A relationship exists between the effective oxygen concentration and burn times reported for a given diameter. The particle burn times measured in this work compare well with other data if the effective oxygen concentration is properly accounted for. Author

HOT JET/WAKE TURBULENT STRUCTURE AND LASER PROPAGAION. PART 1: JET/WAKE TURBULENCE MODELING

Sandy M. Dash and D. C. Kenzakowski *In* JHU, The 21st JANNAF Exhaust Plume Technology Meeting, Volume 1 Oct. 1994 p 59-78 (For primary document see N95-30986 11-34)

(Contract PSR-92-1028-01)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The prediction of laser propagation through the hot turbulent exhaust of an aircraft (or missile) requires knowledge of the detailed turbulent structure, and in particular, density/temperature fluctuations and inner/outer turbulent scales. The ability to predict the mean flow structure of round turbulent jets in an isolated environment has now become well established including hot jets and supersonic jets. However, the ability to predict density or temperature fluctuations and inner scales is poorly established, as is the ability to predict jet interactions with the aerodynamic vorticity (e.g. with the wing-tip vortex). A three-tier program of work has been in progress to enhance our understanding of the turbulent structure in hot jets and its influence on laser propagation. In Part 1 of this paper, the turbulence modeling activities will be described whose basis is the new data being generated at NASA LaRC, to be described in Part 2 of this paper. The kappa epsilon turbulence model and 'g' scalar-fluctuation extension have been implemented in this work. The coefficients of the g-equation have been revised in accordance with new temperature fluctuation data for hot, subsonic jets into still air. Data is now being gathered for hot jets in a co-flow which interact with wing-tip vortices. The inclusion of the g-equation into a Navier-Stokes framework and its analysis of this complex jet data for which detailed turbulence statistics will be available will comprise the main part of this paper. The utility of direct numerical simulation (LES approach to be described in paper by Sinha and Dash) to provide additional insight into this complex problem will also be discussed. Part 2 of this paper discusses the new data, the measurement techniques, and the complexities entailed in data reduction. Part 3 discusses the military applications (laser countermeasures), new laser propagation data through hot jets (as well as new atmospheric turbulence data), and predictive methodology. Author

HOT JET/WAKE TURBULENT STRUCTURE AND LASER PROPAGATION. PART 3: LASER PROPAGATION MEASUREMENTS AND MODELING

Alan R. Shapiro and J. H. Churnside (National Oceanic and Atmospheric Administration, Boulder, CO.) *In* JHU, The 21st JANNAF Exhaust Plume Technology Meeting, Volume 1 Oct. 1994 p 79-95 (For primary document see N95-30986 11-34)

(Contract F33615-92-C-1028)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

The use of lasers aboard aircraft is affected by the perturbed airflow in its vicinity. Therefore, an ability to predict the structure of aircraft-induced turbulence would be useful in system and performance analysis. Pacific-Sierra Research Corp. performed temperature and velocity fluctuation measurements in the wakes of an NRA-3B and a B-1B at trail distances of 50 to 5500 m, at two Mach numbers (0.5 and 0.75) and at two altitudes (0.9 and 6 km). Analysis of the data suggested significant differences with the predictions of the computational fluid dynamics code (CFD) WAKE developed for this application by ARAP for the U.S. Air Force. The magnitude and scales of the temperature fluctuations suggest that first order laser propagation models would not apply. The principal difference between the data and the CFD predictions is that the temperature fluctuations which determine C(n)-2 are not isotropic-and exhibit spectra and correlation scales which differ greatly from those of velocity. This paper reports wind tunnel measurements to determine the source of this temperature structure in aircraft wakes and laser propagation measurements in this regime. Modifications to CFD and to propagation models are suggested. Author

LARGE EDDY SIMULATION OF JETS USING STRUCTURED UPWIND NUMERICS

N. Sinha and Sandy M. Dash *In* JHU, The 21st JANNAF Exhaust Plume Technology Meeting, Volume 1 Oct. 1994 p 97-115 (For primary document see N95-30986 11-34)

(Contract NAS1-19570)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

This paper discusses the analysis of unsteady jets/free shear flows using large eddy simulation (LES) methodology which directly calculates the turbulence large-scale structure and models the higher frequency, finer scales, using subgrid stress (SGS) terms. Fundamental shear layer studies had exhibited the ability of this approach to yield accurate rms values of density/temperature fluctuations (of interest in optical propagation studies), not readily calculable by conventional time-averaged turbulence models. Unsteady phenomena associated with acoustic/turbulence interactions such as vortex shedding are calculable using LES methodology and provide solutions to many complex problems where acoustic waves change the jet structure significantly (e.g. jet passing over a cavity). This paper presents in detail the analysis of a planar, underexpanded Mach 2 jet mixing with quiescent, ambient air. The paper presented the transient features of the rapidly oscillating jets as well as the 'time-averaged' mean flow pattern. Turbulent statistics have been derived by sampling the instantaneous data and spectral characteristics identified. Author

THE PASSAGE FROM TRANSITIONAL TO FREE MOLECULAR PLUMES

James B. Elgin, Edmond Murad (Phillips Lab., Hanscom AFB, MA.), and Charles Pike (Phillips Lab., Hanscom AFB, MA.) *In* JHU, The 21st JANNAF Exhaust Plume Technology Meeting, Volume 1 Oct. 1994 p 117-127 (For primary document see N95-30986 11-34)

(Contract F19628-91-C-0145)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

As DSMC (Direct Simulation Monte Carlo) transition flow plume codes (e.g., SOCRATES or the Monte Carlo modules of CHARM) are applied at increasing altitudes (or decreasing thrusts), the calculations do not always get progressively easier; rather, they tend to reach a 'plateau' of computational difficulty. Unfortunately, this plateau is frequently still a substantial burden for current computers. To address this problem, simplified free molecular models (for example the HAPAIR module of CHARM) have been devised. These models usually consider only first collisions and ignore quenching and molecular motion between the points of excitation and emission. In the case of HAPAIR, there is also an additional simplification made of constant gas-kinetic cross sections. Under the above assumptions, the free molecular models never agree with the Monte Carlo transition flow modules, and the discontinuity between the two predictions has been the source of vexation in the past. The present paper introduces a new free molecular flow model called NOMAD (an acronym for Nonequilibrium Original Monte-Carlo with Approximate Dynamics), which runs two to three orders of magnitude faster than the transition flow Monte Carlo modules, yet agrees with them when applied in the free molecular flow regime. The theory behind this new approach is discussed and sample comparisons are given. Author

VACUUM PLUME BACKFLOW AND RAREFACTION

Gordon R. Scriven and G. N. Freeman *In* JHU, The 21st JANNAF Exhaust Plume Technology Meeting, Volume 1 Oct. 1994 p 129-136 (For primary document see N95-30986 11-34)

Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

Spacecraft surface contamination and sensor interference can result from nozzle-exhaust molecules, droplets, and/or condensate-clusters which expand and scatter to fill the space volume at large angles from the nozzle thrust axis. Only a small fraction of the exhaust products expands

to large angles; however, the amount is sufficient to influence the design and performance of spacecraft sensor platforms which are subject to contamination/interference effects. The large-angle plume mass/species distribution functions depend on (1) the interacting effects of pressure/shear forces and diffusion/rarefaction effects during the rapid angular expansion at the nozzle lip, and (2) the nozzle boundary layer characteristics upstream of the lip expansion. Prediction methods include Euler or Navier-Stokes for continuum regions and direct simulation Monte Carlo (DSMC) for transitional regions. A new formulation was developed which extends the viscous-flow equations (in flow-conformal curvilinear coordinates) to account for flow rarefaction effects. The formulation provides a unified continuous prediction capability which bridges from the continuum region of the nozzle interior to the rarefied region of the plume backflow. Predictions are shown which illustrate the impact of viscous/rarefaction effects on the near-field plume expansion and far-field angular mass flux distribution. Author

COMPARISON OF DSMC PREDICTIONS WITH TEMPORALLY RESOLVED VIBRATIONAL STATE MEASUREMENTS IN NO
Ingrid J. Wysong and David H. Campbell *In* JHU, The 21st JANNAF Exhaust Plume Technology Meeting, Volume 1 Oct. 1994 p 137-142
(For primary document see N95-30986 11-34)
Avail: CPIA, 10630 Little Patuxent Pkwy., Suite 202, Columbia, MD 21044-3200 HC

A laser pump-probe experimental technique has been used to obtain temporally resolved vibrational population distributions in the lower vibrational levels of NO under non-equilibrium conditions. These vibrational population time histories have been compared to direct simulation Monte Carlo predictions in which the vibrational levels are treated as individual chemical species in the calculation. The effects of using species weighting factors in the calculation have also been investigated. Weighting factors will be needed when minor species must be tracked (such as for UV radiation) if large, realistic calculations are to be feasible. However, it appears that the present implementation of weighting factors is seriously flawed. Author

STUDY OF EFFECT OF BUBBLES ON A FREE-SHEAR LAYER Ph.D. Thesis
Sanjeev Kumar 1993 240 p
Avail: Univ. Microfilms Order No. DA9419083

An experimental study of the effect of bubbles on a free shear flow - a mixing layer - has been carried out. The problem of dispersion of particles in a mixing layer has been a topic of extensive research, both experimental and numerical, in the past. Numerical schemes assume a one way coupling between the two phases for dilute solutions i.e., the dynamics of the particles in the shear layer is assumed to be governed by the underlying flow field, but the fluid flow pattern is not modified due to the presence of particles. The objective of these experiments was to investigate whether the presence of particles in the shear layer modifies the flow field in terms of the growth of the mixing layer and the characteristics of the flow field therein. Experiments were performed in a closed loop water tunnel. Quantitative information was obtained using optical flow measurement and visualization techniques. The results show that for a void fraction of 0.5 percent the growth rate of the shear layer is modified in the initial as well as the turbulent region of the shear layer. In the initial region a change in the vortex merging pattern is observed and in the far downstream region the growth rate is observed to increase by as much as 25 percent for certain flow conditions. Different factors which could influence the flow field are discussed. These include the change in density, compressibility, and viscosity of the fluid due to the presence of particles in the flow as well as the change in initial conditions, and the dynamics of bubbles inside the shear layer. No attempt has been made to describe the relative importance of the factors which can be considered significant, because in the experiments it was not possible to isolate the influence of one factor from another. QMR METHODS IN COMPUTATIONAL FLUID DYNAMICS
N. M. Nachtigal and B. D. Semeraro 1995 10 p Presented at the 12th AIAA Computational Fluid Dynamics Conference, San Diego, CA, 19-22 Jun. 1995
(Contract DE-AC05-84OR-21400)
(DE95-010293; CONF-950634-2) Avail: CASI HC A02/MF A01

The authors examine the application of QMR (Quasi-Minimal Residual) methods to the solution of linear systems of equations arising from the use of implicit solution methods in computational fluid dynamics. They will deal with implicit finite difference schemes for solving the Euler equations. These schemes may arise from the implicit treatment of the time dependent equations or from the use of Newton's method for the solution of the steady state equations. In both situations it is necessary to solve a large sparse nonsymmetric linear system of equations at each iteration. They will examine the effectiveness of QMR in the solution of these systems. They compare the resulting methods to methods which rely on some other simplifying technique to solve the linear systems. The goal is to show that the QMR method is a viable alternative to the more ad-hoc schemes for solving implicit computational fluid dynamics problems. DOE

ROLE OF FREE-SURFACE BOUNDARY CONDITIONS AND NONLINEARITIES IN WAVE/BOUNDARY-LAYER AND WAKE INTERACTION Ph.D. Thesis
Jung-Eun Choi 1993 344 p
Avail: Univ. Microfilms Order No. DA9421109

In Part One of this two-part thesis, laminar and turbulent solutions are presented for the Stokes-wave/flat-plate boundary-layer and wake for small - large wave steepness, including exact and approximate treatments of the viscous free-surface boundary conditions. The macro-scale flow exhibits the wave-induced pressure-gradient effects described in a precursory work. For laminar flow, the micro-scale flow indicates that the free-surface boundary conditions have a profound influence over the boundary layer and near and intermediate wake: the wave elevation and slopes correlate with the depthwise velocity; the streamwise and transverse velocities and vorticity display large variations, including islands of maximum/minimum values, whereas the depthwise velocity and pressure indicate small variations; significant free-surface vorticity flux and complex vorticity transport are displayed; wave-induced effects normalized by wave steepness are larger for small steepness with the exception of wave-induced separation; order-of-magnitude estimates are confirmed; and appreciable errors are introduced through approximations to the free-surface boundary conditions. For turbulent flow, the results are similar, but preliminary due to the present uncertainty in appropriate treatment of the free-surface boundary conditions and meniscus boundary layer. In Part Two, Navier-Stokes, boundary-layer, and perturbation expansion solutions are presented for the model problem of a flat-plate boundary layer and wake with temporal, spatial, and traveling horizontal-wave external flows, which are characterized by Stokes-layer overshoots, phase angles, and streaming and nonlinearities. The temporal wave displays close agreement with previous studies and is useful for validation and placing the current work in technical perspective. The spatial wave indicates significantly increased magnitudes and complex nature (e.g., wake bias), which is attributed to nonlinearities associated with large convective acceleration, i.e., nonlinear interaction between the steady and first-harmonic solutions. The traveling wave shows limiting behavior for small and large wave speed of the spatial and temporal waves, respectively, and smooth transition between the two for intermediate values, and extreme wake response for small wave speeds and short wave lengths. In both Parts, implications with regard to practical applications are discussed.

NUMERICAL SIMULATION OF SHOCK/TURBULENT BOUNDARY LAYER INTERACTION Final Year Report
Sedat Biringen and Ferhat F. Hatay [1993] 47 p
(Grant NAG1-1472)
(NASA-CR-198846; NAS 1.26:198846) Avail: CASI HC A03/MF A01

Most flows of aerodynamic interest are compressible and turbulent. However, our present knowledge on the structures and mechanisms of turbulence is mostly based on incompressible flows. In the present work, compressibility effects in turbulent, high-speed, boundary layer flows are systematically investigated using the Direct Numerical Simulation (DNS) approach. Three-dimensional, time-dependent, fully nonlinear, compressible Navier-Stokes equations were numerically integrated by high-order finite-difference methods; no modeling for turbulence is used during the

solution because the available resolution is sufficient to capture the relevant scales. The boundary layer problem deals with fully-turbulent compressible flows over flat geometries. Apart from its practical relevance to technological flows, turbulent compressible boundary layer flow is the simplest experimentally realizable turbulent compressible flow. Still, measuring difficulties prohibit a detailed experimental description of the flow, especially in the near-wall region. DNS studies provide a viable means to probe the physics of compressible turbulence in this region. The focus of this work is to explore the paths of energy transfer through which compressible turbulence is sustained. The structural similarities and differences between the incompressible and compressible turbulence are also investigated. The energy flow patterns or energy cascades are found to be directly related to the evolution of vortical structures which are generated in the near-wall region. Near-wall structures, and mechanisms which are not readily accessible through physical experiments are analyzed and their critical role on the evolution and the behavior of the flow is documented extensively.

SHEAR-FREE TURBULENT BOUNDARY LAYERS Ph.D. Thesis
James Blair Perot 1994 189 p
Avail: Univ. Microfilms Order No. DA9414637

Walls affect turbulence through a number of different mechanisms. The most prominent and well understood mechanism is that due to mean shear. But other, more subtle mechanisms also exist and can be isolated through the study of shear-free boundary layers where the influence of mean shear has been eliminated. In this work, direct numerical simulation on a massively parallel supercomputer (the Connection Machine) is used to investigate the shear-free turbulent boundary layer. The physics of the near wall region and the wall/turbulence interaction is fully investigated and the resulting physical insights are then used to improve near wall turbulence models. Performance comparisons between the Cray Y-MP and the Connection Machine are presented and massively parallel programming issues are discussed. The viscous and kinematic mechanisms of the wall/turbulence interaction are isolated, and a physical model of near wall behavior that is consistent with simulation data is presented. Improved near wall models for the dissipation, pressure-strain, and turbulent transport terms of the Reynolds stress evolution equations are discussed.

EXPERIMENTAL INVESTIGATION OF TURBULENT PARTICLE DISPERSION IN SWIRLING FLOWS Ph.D. Thesis - Ruhr Univ. Bochum [EXPERIMENTELLE UNTERSUCHUNG DER TURBULENTEN PARTIKELDISPERSION IN DRALLSTROEMUNGEN]
Christoph Hassa [1994] 155 p In GERMAN
(ISSN 0939-2963)
(DLR-FB-94-20) Avail: CASI HC A08/MF A02

The turbulent particle dispersion is investigated with regard to the two-phase flow of fuel spray and combustion air in gas turbine combustion chambers. For that purpose, an atmospheric isothermal experiment is presented, that allows the verification of mathematical models for the calculation of turbulent two-phase flows by virtue of the application of nonintrusive measuring techniques and the similarity of its flow configuration to the practical flow. The basic configuration of the gas flow is an axisymmetric, expanding swirl flow with a practical swirl strength and expansion ratio. By using a monodisperse droplet generator, the investigation of turbulent dispersion was separated from atomization. For the gaseous phase, mean and fluctuating velocities as well as Eulerian integral time scales have been measured. The droplet-phase is documented by the measurement of droplet-flux density, velocity, and ensemble rms velocity.

SELF-ADAPTIVE MULTILEVEL METHODS FOR FLUID FLOW PROBLEMS Ph.D. Thesis
Anwar M. Saleh 1994 122 p
Avail: Univ. Microfilms Order No. DA9416309

A computational study of self-adaptive multilevel methods for complex fluid flow problems is made to test the efficiency of these methods. The model problem is time-dependent, nonlinear, convective dominated, and diffusion-limited. Numerical solutions exist, although not multilevel or adaptive ones. A comparison of two adaptive multilevel methods, the multilevel adaptive technique (MLAT) and the fast adaptive composite grid method (FAC), is given to show the possible advantages of the FAC method over the MLAT method by applying them to solve a Poisson equation with an analytical solution. The model problem consists of the quasi-compressible system of the anelastic equations with an initial condition representing a negatively buoyant blob of cold air, which descends to the ground and spreads laterally forming a cold front. A multilevel solution is first obtained on a staggered grid using finite differencing both in time and space. Then the two self-adaptive multilevel methods (MLAT ant FAC) are applied. Numerical results are discussed and compared to numerical solution obtained by Fulton (18) using a Fourier-Chebyshev spectral method with a semi-implicit Runge-Kutta scheme for time integration. Numerical results, as expected, show the FAC is more accurate (at interface) than the MLAT when applied to a Poisson equation. When the self-adaptive versions of the FAC and the MLAT are applied to the complex anelastic equations, computational results show little difference between the two methods and a saving of up to 70 percent in execution time (compared to uniform grid methods of the same accuracy), and when compared to a Fourier-Chebyshev spectral model of the same problem, they are faster for modest accuracy, while the spectral method is faster for higher accuracy.

NUMERICAL SIMULATION OF TIME DEPENDENT VISCOELASTIC FLUID FLOW
Fredrik Olsson [1993] 7 p Prepared in cooperation with Stockholm Univ., Sweden
(TRITA-NA-9311) Avail: CASI HC A02/MF A01

In the last decade, the numerical methods for solving stationary viscoelastic flows have developed rapidly. Many flows with strong viscoelastic or non-Newtonian behavior can be predicted quite accurately. There are however some basic problems remaining to be solved. One is to calculate the flow in irregular geometries, such as the flow around convex corners. Another problems is to predict flow instabilities, which are different from those seen for a Newtonian fluid. Depending on the flow, the introduction of elasticity can both stabilize and destabilize it. Several of the existing methods rely on constitutive equations on differential form, most of which are based on the upper convected Maxwell (UCM) model. The UCM model can be derived from basic assumptions using simple molecular models, continuum mechanical arguments, or physical considerations. However, this constitutive equation is more often used in modified forms which comply better with experiments and behave better numerically. The Giesekus and the PTT model are two popular models which differ from the constitutive equation only in lower order terms, i.e. in terms with no derivatives. Since lower order terms generally do not change the well-posedness properties of a partial differential equation, we will study the UCM model. It enables us to see that this model gives a well-posed system of partial differential equations. We also see why the modified models behave better in numerical computations.

SOME ASPECTS ON THE MODELLING OF NON-NEWTONIAN FLUID FLOW
Jacob Ystroem [1993] 6 p Prepared in cooperation with Stockholm Univ., Sweden
(TRITA-NA-9317) Avail: CASI HC A02/MF A01

Several of the existing models describing viscoelastic fluid flow rely on constitutive equations on differential form. The essential difference of these constitutive equations to the equations describing a Non-Newtonian fluid with a generalized Newtonian constitutive equation, is that a time derivative of the stress tensor is included. This term mimics memory effects for the material, and gives a relaxation model for the stresses. The larger the coefficient is for the time derivative the larger the 'memory' effect is. One of the simplest constitutive equations of this type is the Upper Convected Maxwell (UCM) model. If Newtonian viscosity is also included one obtains the Oldroyd-B model, the up till now mostly used model for viscoelastic fluid flow simulations. The UCM model can be derived from basic assumptions using simple molecular models or continuum mechanics arguments. There is a family of models often used to comply better with

experiments and rheological behavior that are mathematically obtained by adding lower order terms to the UCM model. In this paper we consider a viscoelastic fluid with artificial compressibility and assume a linear relationship between the pressure and the density, where rho(*), and p(*) are constants. (NASA-CR-4679; E-9748; NAS 1.26:4679) Avail: CASI HC A08/MF A02

This report describes two approaches to low Reynolds-number k-epsilon turbulence modeling which formulate the eddy viscosity on the wall-normal component of turbulence and a length scale. The wall-normal component of turbulence is computed via integration of the energy spectrum based on the local dissipation rate and is bounded by the isotropic condition. The models account for the anisotropy of the dissipation and the reduced mixing length due to the high strain rates present in the near-wall region. The turbulent kinetic energy and its dissipation rate were computed from the k and epsilon transport equations of Durbin. The models were tested for a wide range of turbulent flows and proved to be superior to other k-epsilon models, especially for nonequilibrium anisotropic flows. For the prediction of airfoil heat transfer, the models included a set of empirical correlations for predicting laminar-turbulent transition and laminar heat transfer augmentation due to the presence of freestream turbulence. The predictions of surface heat transfer were generally satisfactory. Author

Application of Total Variation Diminishing (TVD) schemes to turbulent flows is considered. The mathematical and physical basis of TVD schemes is discussed. TVD methodology is extended to the solution of turbulent flow problems. A first-order time accurate, second-order space accurate algorithm is used to compute solutions to the problems of shock-boundary-layer interaction, turbine rotor cascade flow, and unsteady, shock-induced heat transfer using the TVD algorithm. This algorithm provides the capability to accurately predict separation, reattachment and pressure and skin friction profiles for shock-boundary-layer inter action. Improved accuracy is demonstrated in computing surface pressures for a turbine rotor cascade. Heat transfer for the cascade is predicted with fair accuracy, showing all the significant features of the experimental Stanton number profile. Fairly accurate comparison with theory and experiment is evident in the unsteady solutions. DTIC

In order to develop a mechanically simple and robust actuator for active flow separation control on axial compressor blades, three different types of acoustic transducers were tested in a wind tunnel. Flow separation on a cylinder in cross flow was used. The first transducer had an internally mounted acoustic speaker blowing through a slot. It could control flow separation only for low Reynolds number laminar flows. A flush mounted high-frequency circular piezo-electric transducer was tried next. It was marginally effective only around the laminar-turbulent transition regime. Since it could not focus the perturbations over a small area, the Acoustosurf was developed next. It consisted of an array of flush mounted narrow strip shaped acoustic transducers capable of detecting surface pressure fluctuations prior to separation. When the appropriate strips were excited at the predominant fluctuation frequency, separation was delayed for transitional and tripped flows. It is believed that the Acoustosurf produces a synergistic interaction between roughness, surface compliance and acoustic radiation to redirect the kinetic energy of the flow by exploiting flow instabilities. Negligible power is therefore needed to operate the Acoustosurf. This has attracted the attention of several aircraft manufacturers. DTIC

The TLNS3DR code is applied to various advanced rotor blades to study tip vortex and to investigate the general capabilities of the code. For nonrotating flows, the solutions in terms of the tip vortex and surface pressure coefficients are obtained for realistic helicopter rotor-tip configurations to study effects of blade planforms on the tip vortex under incompressible flow condition. Calculated results are compared with experimentally obtained data at NASA-Langley's Basic Aerodynamic Research Wind Tunnel (BART). A Berp-type tip, a swept-type tip and its equivalent taper-type tip configurations are investigated. For both nonrotating and rotating flows, the Berp-type blade, the swept-type blade, and its equivalent taper-type and rectangle-type blades with zero twist are considered under compressible flow condition. Solutions are presented. DTIC

COMPRESSIBLE TURBULENCE MEASUREMENT IN LOW-ANGLE INJECTION INTO A SUPERSONIC FLOW M.S. Thesis
Gregory J. McCann Mar. 1995 119 p
(AD-A293836; AFIT/GAE/ENY/95M-03) Avail: CASI HC A06/MF A02

Mean flow and compressible turbulence measurements have been obtained at two stations downstream of low-angle supersonic injection into a Mach 3.0 flow (Re/m = 15 x 10(exp 6)). Data were collected using conventional Pitot and cone-static probes, single and multiple overheat cross-wire anemometry, and flow visualization techniques (shadowgraphs and schlierens). A direct measure of total Reynolds shear stress was accomplished using a turbulence transformation of the Reynolds-averaged Navier-Stokes equations. Results show compressibility effects, indicated by density fluctuations, to be large relative to the velocity fluctuations and on the same order in all three components. Compressibility appears to account for as much as 75% of the total Reynolds shear. The results of the present study suggest turbulent compressibility effects are very important for this class of flows. DTIC

FUNDAMENTAL TOPICS IN HEAT TRANSFER THROUGH DEFORMABLE TWO-PHASE MEDIA Ph.D. Thesis
Alex Jackson Fowler 1993 217 p
Avail: Univ. Microfilms Order No. DA9414128

The reported research focuses on fundamental aspects of convection in a wide variety of media. Chapter 1 investigates the effect of shrinkage during the cooking of meat. Results are reported in the form of dimensionless charts. Comparing these charts with the Heisler charts indicates that shrinkage can have a significant effect on predicted cooking times. Chapter 2 applies contact melting theory to the analysis of sliding on ice. Both pressure melting and viscous heating are taken into account. The results compare favorably with experimental measurements. A method is also proposed to account for ice asperities in the melting model. Chapter 3 is a numerical analysis of natural convection in a porous medium composed of fibers coated with a phase-change material. The results present the time for complete melting of the fiber coatings. It is also shown that these results can be used to predict the solidification time of the fiber coatings. Chapter 4 focuses on trying to develop a universal curve for determining the optimal size of a body with a specified heat transfer duty parameter. The body's optimal size is based either on entropy minimization or cost. Chapter 5 numerically and experimentally investigates the pressure drop and heat transfer in forced convection through tube bundles at low Reynolds numbers, in the fully developed regime, and if the tube bundles are not necessarily perpendicular to the flow direction. It is shown that extrapolation of the available heat exchanger data to this regime results in significant

error. Chapter 6 is a numerical investigation of the effect of a flexible fiber coating on forced convection from a plate in stagnation flow. It is shown that simple relationships exist for predicting the heat transfer coefficient from a surface coated with inflexible fibers; and that fiber bending does not have a large impact on the heat transfer coefficient for the cases studied. APPLICATION OF WAVELET-FILTERING TECHNIQUES TO INTERMITTENT TURBULENT AND WALL PRESSURE EVENTS. PART 2. DETECTION OF CLUSTER PATTERNS Progress Report, Nov. 1994 - Nov. 1995

Mario J. Casarella, Pablo B. Penafiel, and Mark E. Kammeyer 26 Apr. 1995 62 p

(Contract N00014-88-K-0141)

(AD-A293805) Avail: CASI HC A04/MF A01

Large amplitude wall-pressure events, observed beneath a turbulent boundary layer, appear to be signatures of intermittent organized motions within the turbulent flow. Experimental studies were made investigating this relationship. Part 1 presented the first phase of this investigation and reported on the results of utilizing time-frequency localization techniques (wavelet transforms) for the detection of these events. The application of wavelet filtering for the analyses of turbulent data was introduced. This report presents the results of the second phase of the investigation. A wavelet filter was selected based on maintaining the integrity of intermittent near wall burst events. The correlations between individual turbulent flow and wall-pressure events were confirmed using both the original time records and the generated VITA function time records. A localized windowed peak detection algorithm was developed that detects the groupings of these events. The algorithm detects the temporal locations and durations of the clusters. Correlation and conditional sampling methods were then used to postulate the sequential burst events contained within the individual clusters. Conditional sampling showed a bidirectional relationship between positive wall-pressure events and burst ejections in the near-wall region. DTIC

LARGE-EDDY SIMULATION OF TURBULENT FLOW USING THE FINITE ELEMENT METHOD Ph.D. Thesis

R. C. McCallen 15 Feb. 1995 346 p

(Contract W-7405-eng-48)

(DE95-009464; UCRL-LR-114962) Avail: CASI HC A15/MF A03

The equations of motion describing turbulent flows (in both the low and high Reynolds-number regimes) are well established. However, present day computers cannot meet the enormous computational requirement for numerically solving the governing equations for common engineering flows in the high Reynolds number turbulent regime. The characteristics that make turbulent, high Reynolds number flows difficult to simulate is the extreme range of time and space scales of motion. Most current engineering calculations are performed using semi-empirical equations, developed in terms of the flow mean (average) properties. These turbulence 'models' (semi-empirical/analytical approximations) do not explicitly account for the eddy structures and thus, the temporal and spatial flow fluctuations are not resolved. In these averaging approaches, it is necessary to approximate all the turbulent structures using semi-empirical relations, and as a result, the turbulence models must be tailored for specific flow conditions and geometries with parameters obtained (usually) from physical experiments. The motivation for this research is the development of a finite element turbulence modeling approach which will ultimately be used to predict the wind flow around buildings. Accurate turbulence models of building flow are needed to predict the dispersion of airborne pollutants. The building flow turbulence models used today are not capable of predicting the three-dimensional separating and reattaching flows without the manipulation of many empirical parameters. These empirical parameters must be set by experimental data and they may vary unpredictably with building geometry, building orientation, and upstream flow conditions. DOE

PARTICLE FILTRATION: AN ANALYSIS USING THE METHOD OF VOLUME AVERAGING

M. Quintard and S. Whitaker Dec. 1994 53 p

(Contract W-7405-eng-48)

(DE95-009467; UCRL-CR-119484) Avail: CASI HC A04/MF A01

The process of filtration of non-charged, submicron particles is analyzed using the method of volume averaging. The particle continuity equation is represented in terms of the first correction to the Smoluchowski equation that takes into account particle inertia effects for small Stokes numbers. This leads to a cellular efficiency that contains a minimum in the efficiency as a function of the particle size, and this allows us to identify the most penetrating particle size. Comparison of the theory with results from Brownian dynamics indicates that the first correction to the Smoluchowski equation gives reasonable results in terms of both the cellular efficiency and the most penetrating particle size. However, the results for larger particles clearly indicate the need to extend the Smoluchowski equation to include higher order corrections. Comparison of the theory with laboratory experiments, in the absence of adjustable parameters, provides interesting agreement for particle diameters that are equal to or less than the diameter of the most penetrating particle. DOE

PARTICLE FILTRATION: A COMPARISON BETWEEN THEORY AND EXPERIMENT

M. Quintard and S. Whitaker Dec. 1994 35 p Presented at the Encontro Sobre Escoamento Em Meios Porosos, Floriaopolis, Brazil, 19-21 Oct. 1994

(Contract W-7405-eng-48)

(DE95-009442; UCRL-JC-119485; CONF-9410330-1) Avail: CASI HC A03/MF A01

The process of filtration of non-charged, submicron particles represents an example of transport in homogeneous and heterogeneous porous media that can be analyzed using the method of volume averaging. In this article the authors develop the local volume averaged particle transport equation for a homogeneous filter and compare the results with experimental data. The particle continuity equation is represented in terms of the first correction to the Smoluchowski equation that takes into account particle inertia effects for small Stokes numbers. This leads to a cellular efficiency that contains a minimum in the efficiency as a function of the particle size, and this allows them to identify the most penetrating particle size. Comparison of the theory with experimental results indicates that the first correction to the Smoluchowski equation gives reasonable results for the most penetrating particle size and for smaller particles; however, results for larger particles clearly indicate the need to extend the Smoluchowski equation to include higher order corrections. The influence of local heterogeneities on the measured filter efficiency may account for some of the observed differences between theory and experiment. DOE

ON THE INTERACTIONS BETWEEN PARTICLES AND TURBULENCE IN A FULLY-DEVELOPED CHANNEL FLOW IN AIR Ph.D. Thesis

Johathan D. Kulick 1994 215 p

Avail: Univ. Microfilms Order No. DA9414602

The interactions between small, dense particles and fluid turbulence have been investigated in a downflow, fully-developed channel in air. The particles were selected to respond to some but not all of the scales of turbulent motions. Particle velocities and concentration fields were examined to determine particle response to turbulence. Gas-phase velocities were measured to investigate turbulence modification by particles; particle relaxation time and mass loading were varied. The channel flow was at Reynolds number 13,800. Three classes of narrowly sized spherical beads were used: 50 micron and 90 micron diameter glass beads and 70 micron diameter copper shot. The particles were smaller than the Kolmogorov scale of turbulence; particle relaxation times ranged from 18 ms to 95 ms. Particle mass loadings ranged up to 0.8 yet particle volume fractions remained under 0.02 percent. Particle and gas-phase velocities were measured by LDA, with pedestal amplitude discrimination. Particle concentration fields were determined from computer processed laser flow visualization (these experiments also used 25 micron glass beads and Lycopodium powder). Particle mean velocity profiles were flatter than air velocity profiles. Streamwise particle velocity fluctuation intensities were larger than the corresponding fluid turbulence intensities, while the opposite behavior was observed in the transverse direction. Particle number density distributions furnished evidence of preferential concentration of particles by

turbulence, previously observed in the computational studies of Squires and Eaton. Gas-phase mean velocity profiles exhibited no effects of particle loading, with the air mass flow-rate held constant. Turbulence attenuation increased with both particle mass loading and particle relaxation time, with reductions in turbulence kinetic energy of up to 80 percent. Particles at low mass loadings attenuated turbulence more strongly in the transverse than in the streamwise direction, which is attributed to the different turbulence spectra seen by the particle in the two directions. Turbulence attenuation increased with distance from the wall. Estimates of the contribution of particles to the dissipation of turbulence kinetic energy, based on k-epsilon models, showed that smaller relative increases in dissipation in channel flow, compared with those in forced isotropic turbulence, corresponded to larger reductions of turbulence intensity. Dissert. Abstr.

HEAT TRANSFER IN SHEAR-FREE TURBULENT BOUNDARY LAYERS Ph.D. Thesis
Paul Malan 1994 256 p
Avail: Univ. Microfilms Order No. DA9414613

Shear-free turbulent boundary layers are idealized near-surface flows without gradients in mean velocity. Direct numerical simulation was used to investigate passive-scalar (temperature) transport in these flows. The configuration corresponds to the sudden insertion of infinite, impermeable surfaces into turbulence that was previously isotropic, homogeneous, and at a different, uniform temperature. The study is relevant to: (1) effects of ultra-high free-stream turbulence intensities on surface heat-transfer and (2) scalar transport at the free surfaces of turbulent liquids. It is an important limiting case for turbulent heat transfer models, since the Reynolds analogy fails totally and there is no production of turbulence. Two hydrodynamic boundary conditions were considered: a simulated solid surface and an idealization of a clean, undisturbed, free surface. Statistics are presented for an initial turbulent Reynolds number (Re(sub t) is identical with k(exp 2)/(epsilon nu)) of approximately 150; Prandtl numbers of 0.1, 0.71, and 2; and a constant-temperature thermal boundary condition. Additional data are included for initial turbulent Reynolds numbers of 60 and 380. Visualizations of the instantaneous fields illustrate the turbulent structures that augment the heat transfer. At least one eddy-turnover time after the surfaces are introduced, the heat transfer is governed by turbulent transport (if the turbulent Peclet number is high enough). The heat-transfer coefficient is related to the inverse of the far-field Kolmogorov length-scale for a given fluid Prandtl number and initial turbulence spectrum. Previously reported studies on scalar transport at free surfaces support this finding. A generalized gradient-diffusion model for the turbulent heat-flux was tested. The model appears adequate for the turbulent Peclet numbers considered. Detailed budgets of the terms in the transport equation for the turbulent heat-flux were used to investigate near-surface heat-flux closure hypotheses. New suggestions were made for modeling the diffusive and dissipative correlations. Current models for the turbulent-transport terms do not work well in this situation. The simulation data enable the scalar-pressure gradient correlation to be examined in the absence of any contribution from mean strain. Dissert. Abstr.

CONTROL OF HIGH REYNOLDS NUMBER ROUND JETS Ph.D. Thesis
Philippe Jean-Daniel Juvet 1994 216 p
Avail: Univ. Microfilms Order No. DA9414588

The entrainment and mixing ability of jets are of particular interest in propulsion and combustion systems. The present work concentrates on the experimental investigation of active and passive techniques for control of high Reynolds number jets. Three control techniques were considered; (1) dual-mode dual-frequency acoustic excitation, (2) tangential blowing along an axisymmetric curved wall, and (3) self-excitation. The basic flow was an air jet, with an exit diameter of 20 mm, at Reynolds numbers between 20,000 and 120,000. The flow was studied by hot-wire anemometry and flow visualization. The development of a round jet can be altered significantly by a combined axial-helical acoustic forcing. Entrainment was estimated, using a shroud placed around the jet, at a Reynolds number of 100,000 and for various levels of axial and helical forcing. Dual-mode excitation was shown to increase entrainment by a factor of up to 2.4, which could not be achieved by axial excitation only. Exit shear-layer manipulation did not ease the forcing requirements. The flow produced by tangential blowing along an axisymmetric curved wall placed around the jet exhibits two regimes, depending on the blowing ratio. For a subcritical blowing ratio, the flow is jet-like, whereas for a supercritical blowing ratio, the jet is entirely diverted radially and develops further as a radial wall jet. The key mechanism for this dramatic change of topology was shown to be entrainment. The critical blowing ratio is almost independent of the Reynolds number and lies around 10 percent. A family of exit geometries was found to induce jet self-excitation, which appears attractive as a replacement to external axial acoustic forcing. The main characteristics of these geometries are a sudden cross-section increase (backstep) at the contraction termination, followed by a curved-wall diffuser, and an axisymmetric cavity connected to the backstep. The axial oscillation of the flow separation on the curved wall causes the regular production of vortex rings, as in an axially-excited jet. The oscillation dominant frequency is proportional to the jet throughflow velocity leading to a constant Strouhal number (between 0.2 and 0.4). This Strouhal number depends mainly on the wall radius of curvature. Dissert. Abstr.

EXPERIMENTAL AND COMPUTATIONAL INVESTIGATION OF THE TIP CLEARANCE FLOW IN A TRANSONIC AXIAL COMPRESSOR ROTOR
Kenneth L. Suder and Mark L. Celestina (Sverdrup Technology, Inc., Brook Park, OH.) Jun. 1995 17 p Presented at the 39th International Gas Turbine and Aeroengine Congress and Exposition, The Hague, Netherlands, 13-16 Jun. 1994, sponsored by ASME
(Contract NAS3-25266; RTOP 505-62-52)
(NASA-TM-106711; E-9076; NAS 1.15:106711) Avail: CASI HC A03/MF A01

Experimental and computational techniques are used to investigate tip clearance flows in a transonic axial compressor rotor at design and part speed conditions. Laser anemometer data acquired in the endwall region are presented for operating conditions near peak efficiency and near stall at 100% design speed and at near peak efficiency at 60% design speed. The role of the passage shock/leakage vortex interaction in generating endwall blockage is discussed. As a result of the shock/vortex interaction at design speed, the radial influence of the tip clearance flow extends to 20 times the physical tip clearance height. At part speed, in the absence of the shock, the radial extent is only 5 times the tip clearance height. Both measurements and analysis indicate that under part-speed operating conditions a second vortex, which does not originate from the tip leakage flow, forms in the endwall region within the blade passage and exits the passage near midpitch. Mixing of the leakage vortex with primary flow downstream of the rotor at both design and part speed conditions is also discussed. Author

SELECTED FLOWS WITH FREE SURFACES: STREAMS AND DROPS [WYBRANE PRZEPLYWY ZE SWOBODNA POWIERZCHNIA: STRUGI I KROPLE]
Tomasz A. Kowalewski Mar. 1995 96 p In POLISH
(ISSN 0208-5658)
(IFTR-3/1995) Avail: CASI HC A05/MF A01

The basic purpose of the research described in this article was to develop a non contact method for diagnosing the physical parameters of the free surface of a liquid using drop oscillation analysis. In particular, the purpose is to measure the temperature of an evaporating surface. The realization of this goal has led to the development of new experimental techniques which make it possible to record fast processes using video and digital imaging equipment. Experimental studies of the process of the formation of drops as a result of the controlled breakup of a stream revealed the existence of an additional phase in the process based on the formation of microstreams and microsatellites with micrometer-like dimensions. A comparison of measurement results with Eggers' asymptotic model (23) confirmed the model's basic assumption of the local nature of the final phase in the disintegration of the stream, which at the same time points to the existence of a number of discrepancies which provide evidence of the limitations of this approximation. The next part of the article presents the results of observations of the instability of streams of liquid caused by its evaporation. In an attempt to analyze the mechanisms which initiate the turbulence of the evaporating surface, the author focused on surface tension gradients as an essential factor in the destabilization of

small-diameter streams. The author also described the occurrence of a number of new phenomena in the destabilization of a stream, including the separation of surface fragments, their stabilization by the flow of vapor, and a quasistable change in the trajectory of the stream. The author also developed an experimental method which makes it possible to detect and produce a precise description of the deformation of drops. Measurements of the oscillations of small drops in the air led to the development of a complete non-linear model of the oscillations of a viscous drop and made it possible to verify simplified models. The author presents examples which demonstrate the possibility of using the oscillating drop method to study the physical properties of the liquid and determine the temperature and composition of the surfaces of evaporating drops. UNSTEADY FLOW SIMULATIONS ABOUT MOVING BOUNDARY CONFIGURATIONS USING DYNAMIC DOMAIN DECOMPOSITION TECHNIQUES Ph.D. Thesis
Guan-Wei Yen 1994 155 p
Avail: Univ. Microfilms Order No. DA9423440

A computational method is developed to solve the coupled governing equations of an unsteady flowfield and those of rigid-body dynamics in six degrees-of-freedom (6-DOF). This method is capable of simulating the unsteady flowfields around multiple component configurations with at least one of the components in relative motion with respect to the others. Two of the important phenomena that such analyses can help us to understand are the unsteady aerodynamic interference and the boundary-induced component of such a flowfield. By hybridizing two dynamic domain decomposition techniques, the grid generation task is simplified, the computer memory requirement is reduced, and the governing equations of the rigid-body dynamics are simplified with certain assumptions. Three dimensional, unsteady Navier-Stokes equations are solved on each of the subdomains by a fully-vectorized, finite-volume, upwind-biased, and approximately-factored method. These equations are solved on the composite meshes of hybrid subdomain grids that can move with respect to each other. Hence, the present method combines the advantages of an efficient, geometrically conservative, minimally and automatically dissipative algorithm with the advantages and flexibility of the domain decomposition techniques. Several measures that reduce the numerical error are studied and compared with the exact solution of a moving normal shock in a tube. This solution compares very well with the analytic solution of the isentropic equations. It is concluded, that as a minimum measure, the connectivity of nonconservative overlapped scheme needs to be second-order accurate for spatial and temporal discretizations, as well as for the moving subdomain interpolations. Furthermore, the CFL numbers should be restricted to below unity, if affordable, for flows with high flow gradients. The method is further scrutinized by simulating the flow past a sinusoidally pitching airfoil, and the flow past a sinusoidally pitching and plunging airfoil. The results of the former case are successfully compared with the experimental data. The final two-dimensional case is the separation of a store from an airfoil along a prescribed path. As the first three dimensional case, the flowfield past an oscillating cylinder near a vertical wall is simulated. Prior to coupling it with the flowfield equations, the 6-DOF trajectory method is validated by successfully comparing the path it predicts with the one used in a captive trajectory testing. Finally, a rigid-body dynamics method is used to predict the aerodynamically determined trajectory of a store dropped from its initial position under a wing. The results of the present investigation contribute to the understanding of the unsteady aerodynamic interference and the boundary-induced component of such a flowfield. However, its main contribution is the newly proposed computational method for flows involving relative boundary motions. Dissert. Abstr.

ANALYSIS AND MODELING OF SUBGRID SCALAR MIXING USING NUMERICAL DATA Final Report
Sharath S. Girimaji and Ye Zhou May 1995 32 p Submitted for publication in Physics of Fluids
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-198169; NAS 1.26:198169; ICASE-95-44) Avail: CASI HC A03/MF A01

Direct numerical simulations (DNS) of passive scalar mixing in isotropic turbulence is used to study, analyze and, subsequently, model the role of small (subgrid) scales in the mixing process. In particular, we attempt to model the dissipation of the large scale (supergrid) scalar fluctuations caused by the subgrid scales by decomposing it into two parts: (1) the effect due to the interaction among the subgrid scales; and (2) the effect due to interaction between the supergrid and the subgrid scales. Model comparisons with DNS data show good agreement. This model is expected to be useful in the large eddy simulations of scalar mixing and reaction. Author

(DE95-009810; CONF-950431-1) Avail: CASI HC A02/MF A01

PHOENICS is a suite of computational analysis programs that are used for simulation of fluid flow, heat transfer, and dynamical reaction processes. The parallel version of the solver EARTH for the Computational Fluid Dynamics (CFD) program PHOENICS has been implemented using Message Passing Interface (MPI) standard. Implementation of MPI version of PHOENICS makes this computational tool portable to a wide range of parallel machines and enables the use of high performance computing for large scale computational simulations. MPI libraries are available on several parallel architectures making the program usable across different architectures as well as on heterogeneous computer networks. The Intel Paragon NX and MPI versions of the program have been developed and tested on massively parallel supercomputers Intel Paragon XP/S 5, XP/S 35, and Kendall Square Research, and on the multiprocessor SGI Onyx computer at Oak Ridge National Laboratory. The preliminary testing results of the developed program have shown scalable performance for reasonably sized computational domains. DOE

NUMERICAL SIMULATION OF THE LANGEVIN EQUATION FOR SKEWED TURBULENCE
Donald L. Ermak and John S. Nasstrom Dec. 1994 8 p Presented at the 11th Symposium on Boundary Layers and Turbulence, Charlotte, NC, 27-31 Mar. 1995 Prepared in cooperation with EG and G Energy Measurements, Inc., Pleasanton, CA
(Contracts DE-AC08-93NV-11265; W-7405-eng-48)
(DE95-009477; UCRL-JC-118404; CONF-950381-1) Avail: CASI HC A02/MF A01

In this paper the authors present a numerical method for the generalized Langevin equation of motion with skewed random forcing for the case of homogeneous, skewed turbulence. The authors begin by showing how the analytic solution to the Langevin equation for this case can be used to determine the relationship between the particle velocity moments and the properties of the skewed random force. They then present a numerical method that uses simple probability distribution functions to simulate the effect of the random force. The numerical solution is shown to be exact in the limit of infinitesimal time steps, and to be within acceptable error limits when practical time steps are used. DOE

SPATIALLY-RESOLVED VELOCITY MEASUREMENTS IN STEADY, HIGH-SPEED, REACTING FLOWS USING LASER-INDUCED OH FLUORESCENCE Ph.D. Thesis
Kurt G. Klavuhn 1994 180 p
Avail: Univ. Microfilms Order No. DA9424479

The theoretical development and calibration of a nonintrusive, high-resolution, optical flowfield-diagnostic technique utilizing OH laser-induced fluorescence (OH LIF) for the measurement of velocity in steady, high-speed, reacting flows is reported. The particular high-speed, reacting flows of interest are those occurring in supersonic combustors for proposed hypersonic flight vehicles. The theory of the OH LIF strategy employed is described, with emphasis on the optimization of the strategy for quantitative velocity measurements. A simplified model is derived for the calculation of expected signal levels from pulsed, narrow-linewidth,

(1,0) band excitation of OH in flames when collecting filtered (1,1) and (0,0) band fluorescence with a gated detector. Several illumination techniques are presented for measuring the Doppler shift of the OH LIF while eliminating systematic errors. A unique reacting underexpanded jet was constructed for the calibration of the OH LIF velocity measurement technique over a wide range of flow conditions. A complete analysis of the distribution of flow properties in the jet flowfield is presented, including results from a full Navier-Stokes calculation with finite-rate chemistry. Comparisons of results from pointwise OH LIF velocity measurements along the centerline and planar OH LIF velocity measurements along the central plane of the reacting underexpanded jet with the numerical solution demonstrate the resolution, range, and accuracy of the technique. Measured and calculated velocities in the supersonic jet core agree on average to within +/- 1.3 percent for the pointwise measurements and +/- 2.2 percent for the planar measurements. The uncertainty (2 sigma) in the pointwise velocity measurements in the jet core was on average +/- 6.0 percent for a single measurement and +/- 3.5 percent for the average value of three scans. For the planar velocity measurements in the jet core, the uncertainty (2 sigma) was on average +/- 4.9 percent for a single measurement and +/- 2.2 percent for the average value of five scans. Dissert. Abstr.

AN EFFICIENT NUMERICAL PROCEDURE FOR THERMOHYDRODYNAMIC ANALYSIS OF CAVITATING BEARINGS Final Contractor Report
D. Vijayaraghavan Jul. 1995 26 p Presented at the 1995 Tribology Conference, Kissimmee, FL, 8-11 Oct. 1995; sponsored by the Society of Tribologists and Lubrication Engineers and the ASME
(Contract NCC3-291; RTOP 505-62-10; DA Proj. 1L1-61102-AH-45)
(NASA-CR-195476; E-9692; NAS 1.26:195476; ARL-CR-237) Avail: CASI HC A03/MF A01

An efficient and accurate numerical procedure to determine the thermo-hydrodynamic performance of cavitating bearings is described. This procedure is based on the earlier development of Elrod for lubricating films, in which the properties across the film thickness are determined at Lobatto points and their distributions are expressed by collocated polynomials. The cavitated regions and their boundaries are rigorously treated. Thermal boundary conditions at the surfaces, including heat dissipation through the metal to the ambient, are incorporated. Numerical examples are presented comparing the predictions using this procedure with earlier theoretical predictions and experimental data. With a few points across the film thickness and across the journal and the bearing in the radial direction, the temperature profile is very well predicted. Author

OPTIMAL HEAT TRANSFER DESIGN OF CHEMICAL VAPOR DEPOSITION REACTORS
Christopher D. Moen, Paul A. Spence, and Juan C. Meza Apr. 1995 29 p
(Contract DE-AC04-94AL-85000)
(DE95-010997; SAND-95-8223) Avail: CASI HC A03/MF A01

A new tool for optimal heat transfer design has been constructed by coupling the OPT++ optimization library to the TAC02D finite element heat transfer code. The optimization heat transfer code can be used to quickly and efficiently find optimal operating parameters required for target design criteria. This tool has been applied to the heat transfer design of a rotating disk chemical vapor deposition reactor. The results from two reactor design problems indicate that optimal solutions can be found quickly and efficiently. DOE

(Contract DE-AC03-76SF-00098)
(DE95-008447; LBL-36274; CONF-9411173-6) Avail: CASI HC A02

We present measurements of a 4 element PET detector module that uses a 2 x 2 array of 3 mm square PIN photodiodes to both measure the depth of interaction (DOI) and identify the crystal of interaction. Each photodiode is coupled to one end of a 3 x 3 x 25 mm LSO crystal, with the opposite ends of all 4 crystals attached to a single PMT that provides a timing signal and initial energy discrimination. Each LSO crystal is coated with a 'lossy' reflector, so the ratio of light detected in the photodiode and PMT depends on the position of interaction in the crystal, and is used to determine this position on an event by event basis. This module is operated at +25 C photodiode amplifier peaking time of 2 micro s. micro s. When excited by a collimated beam of 511 photons at the photodiode end of the module (i.e. closest to the patient), the DOI resolution is 4 mm fwhm and the crystal of interaction is identified correctly 95% of the time. When excited at the opposite end of the module, the DOI resolution is 13 mm fwhm and the crystal of interaction is identified correctly 73% of the time. The channel to channel variations in performance are minimal. DOE

(DE95-008540; SAND-94-2193C; CONF-950228-4) Avail: CASI HC A02/MF A01

An overview of the major sensor and actuator projects using the micromachining capabilities of the Microelectronics Development Laboratory at Sandia National Laboratories is presented. Development efforts are underway for a variety of micromechanical devices and control electronics for those devices. Surface micromachining is the predominant technology under development. Pressure sensors based on silicon nitride diaphragms have been developed. Hot polysilicon filaments for calorimetric gas sensing have been developed. Accelerometers based upon high-aspect ratio surface micromachining are under development. Actuation mechanisms employing either electrostatic or steam power are being combined with a three-level active (plus an additional passive level) polysilicon surface micromachining process to couple these actuators to external devices. Results of efforts toward integration of micromechanics with the driving electronics for actuators or the amplification/signal processing electronics for sensors is also described. This effort includes a tungsten metallization process to allow the CMOS electronics to withstand high-temperature micromechanical processing. DOE

RESULTS FROM TESTS OF THE KEARFOTT T16-B INERTIAL MEASUREMENT UNIT
B. Jalving 6 Jan. 1995 87 p
(PB95-212031) Avail: CASI HC A05/MF A01

The Norwegian Defense Research Establishment (NDRE) has tested Kearfott Guidance & Navigation Corporation's T16-B Inertial Measurement Unit (IMU) as part of a program for investigating alternative technologies and vendors for the new antiship missile for the Royal Norwegian Navy. Two different IMU's were tested. Among the tests carried out were static navigation, gyro compassing, dynamic navigation, performance during vibrations and determination of gyro random walk coefficients, accelerometer biases and gyro biases. Additionally the applicability of the IMU navigation data for seeker stabilization has been investigated. Significant difference in performance between the two tested units and dependence on the flight profile were observed. The results obtained indicate that the Kearfott T16-B IMU is well suited for the new antiship missile. NTIS

(DE95-008829; UCRL-JC-118213; CONF-940723-36) Avail: CASI HC A03/MF A01

X-ray calibration of the Electro-Optical Breadboard Model (EOBB) of the XXM Reflection Grating Spectrometer has been carried out at the Panter test facility in Germany. The EOBB prototype optics consisted of a four-shell grazing incidence mirror module followed by an array of eight reflection gratings. The dispersed x-rays were detected by an array of three CCD's. Line profile and efficiency measurements where made at several energies, orders, and geometric configurations for individual gratings and for the grating array as a whole. The x-ray measurements verified that the grating mounting method would meet the stringent tolerances necessary for the flight instrument. Post EOBB metrology of the individual gratings and their mountings confirmed the precision of the grating boxes fabrication. Examination of the individual grating surface's at micron resolution revealed the cause of anomalously wide line profiles to be scattering due to the crazing of the replica's surface. DOE

FABRY-PEROT INTERFEROMETER MEASUREMENT OF STATIC TEMPERATURE AND VELOCITY FOR ASTOVL MODEL TESTS
Helen E. Kourous and Richard G. Seacholtz Jul. 1995 8 p Presented at the Symposium on Laser Anemometry: Advances and Applications, Lake Tahoe, NV, 19-23 Jun. 1994; sponsored by ASME
(RTOP 505-62-50)
(NASA-TM-107014; E-9799; NAS 1.15:107014) Avail: CASI HC A02/MF A01

A spectrally resolved Rayleigh/Mie scattering diagnostic was developed to measure temperature and wing-spanwise velocity in the vicinity of an ASTOVL aircraft model in the Lewis 9 x 15 Low Speed Wind Tunnel. The spectrum of argon-ion laser light scattered by the air molecules and particles in the flow was resolved with a Fabry-Perot interferometer. Temperature was extracted from the spectral width of the Rayleigh scattering component, and spanwise gas velocity from the gross spectral shift. Nozzle temperature approached 800 K, and the velocity component approached 30 m/s. The measurement uncertainty was about 5 percent for the gas temperature, and about 10 m/s for the velocity. The large difference in the spectral width of the Mie scattering from particles and the Rayleigh scattering from gas molecules allowed the gas temperature to be measured in flow containing both naturally occurring dust and LDV seed (both were present). FOG [MAETNINGAR PA FIBEROPTISKT GYRO]
S. Arnzen and U. Ekstroem Nov. 1994 42 p In SWAHILI
(PB95-211546; FOA-R-94-00055-8.4-SE) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report gives an account of results from an evaluation test of a fiber optic gyroscope (FOG) with the use of a recently modified gyro rate table of one-axis design. The gyro of single axis rate type is an Alcatel Standard Electrik Loren (SEL) design with designation PM1DE 90/00079. It is a first generation FOG from the German company SEL with all electronics collected on a separate so called European standard PCB card. The purpose of the test is to enhance our competence of knowledge within the field of modern gyros, where FOG's are of special interest as future sensors in weapon systems of different kinds. The results seem to be in good agreement with the SEL specifications for the most important parameters of bias uncertainty, scale factor, linearity, input range, and noise. Only concerning the variation of the scale factor with temperature, disagreement was noticeable at the high temperature end. NTIS

FIBER OPTIC ACCELEROMETER WITH CENTRALLY SUPPORTED FLEXURAL DISK Patent
Thomas J. Hofler, inventor (to Navy), David A. Brown, inventor (to Navy), and Steven L. Garrett, inventor (to Navy) 29 Nov. 1994 8 p Filed 9 Dec. 1993
(AD-D017369; US-Patent-5,369,485; US-Patent-Appl-SN-163789; US-Patent-Class-356-345) Avail: US Patent and Trademark Office

An accelerometer or seismometer has an elastic disk bearing a mass distributed peripherally around the disk. The disk is supported for flexure and for isolation from mounting strain by a stob centrally through the disk. The accelerometer or seismometer has a pair of flat spirals of optical fiber, each spiral being fixedly attached to a corresponding disk side so that disk flexure lengthens a spiral on one disk side and shortens a spiral on an oppositely facing disk side and so that temperature differences between the spirals are minimized. The pair of spirals are connected as legs of a fiber optic interferometer so that the interferometer provides an output corresponding to the flexure. Several of the disks and associated pairs of spirals may be coaxially mounted to provide increased sensitivity. DTIC

METROLOGY OF CHROME ON QUARTZ PHOTOMASKS USING LOW VOLTAGE SCANNING ELECTRON MICROSCOPY. PART 1: PHYSICAL SEM PARAMETERS
B. H. Bracher and R. Jonckheere Jan. 1995 29 p Prepared in cooperation with Interuniversity Micro-Electronics Center, Leuven, Belgium
(PB95-195780; RAL-95-011-Pt-1) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report is the first of two, describing work done under the JESSI T8 Project on scanning electron microscopy (SEM) metrology of Cr/quartz photomasks. It outlines the T8 Project itself and describes in detail the determination of optimum physical parameters for low voltage SEM inspection. In addition, correlation with optical measurements is described. A second report deals with further optimization of SEM usage in photomask metrology. NTIS

OPTIMIZATION OF A THERMOELECTRIC IR-DETECTOR FOR LOW WORKING TEMPERATURE
R. Fettig, H. J. Lerchenmueller, and E. Mueller 1993 5 p
(Contract NASw-4685)
(NASA-CR-198933; NAS 1.26:198933) Avail: CASI HC A01/MF A01

Thermoelectric IR-detectors have been developed for working at a temperature of 170 K in the CIRS experiment of the designated interplanetary CASSINI mission. Thermoelectric legs of p- and n-type are soldered isolated one from another to a metallized ceramic substrate. Pyramidal legs are formed by electric discharge machining (EDM). A thin gold foil is welded to the cones and blackened for high absorption of radiation. Characterization measurements are carried out to correlate detector properties with the influence of preparation process and material used. Thermoelectric behaviour is described by measuring the current-voltagecharacteristics from liquid nitrogen up to room temperature. Material of various composition within the pseudobinary systems Bi2Te3-Sb2Te3 (for p-type) and Bi2Te3-Bi2Se3 (for n-type) has been used for detector preparation. By choosing material of proper doping the maximum of the figure of merit could be shifted towards lower temperatures. Author

A LASER-BASED ICE SHAPE PROFILOMETER FOR USE IN ICING WIND TUNNELS
Edward A. Hovenac (NYMA, Inc., Brook Park, OH.) and Mario Vargas Jun. 1995 25 p Original contains color illustrations
(Contract NAS3-27186)
(NASA-TM-106936; E-9864; NAS 1.15:106936) Avail: CASI HC A03/MF A01; 1 functional color page

A laser-based profilometer was developed to measure the thickness and shape of ice accretions on the leading edge of airfoils and other models in icing wind tunnels. The instrument is a hand held device that is connected to a desk top computer with a 10 meter cable. It projects a laser line onto an ice shape and used solid state cameras to detect the light scattered by the ice. The instrument corrects the image for camera angle distortions, displays an outline of the ice shape on the computer screen, saves the data on a disk, and can print a full scale drawing of the ice shape. The profilometer has undergone extensive testing in the laboratory and in the NASA Lewis Icing Research Tunnel. Results of the tests show very good agreement between profilometer measurements and known simulated ice shapes and fair agreement between profilometer measurements and hand tracing techniques. ON THE USE OF ELECTRONIC TILT SENSORS AS ANGLE ENCODERS FOR SYNCHROTRON APPLICATIONS
G. S. Knapp, H. You, and Gary R. Holzhausen (Applied Geomechanics, Inc., Santa Cruz, CA.) Sep. 1994 12 p Presented at the International Meeting on Synchrotron Radiation Instrumentation, Stony Brook, NY, 18-22 Jul. 1994 Submitted for publication in Review of Scientific Instruments
(Contract W-31-109-eng-38)
(DE95-005836; ANL/MSD/CP-82825; CONF-940714-53) Avail: CASI HC A03/MF A01

The authors have tested several electrolytic tilt sensors produced by Applied Geomechanics Inc. A pair of sensors were tested by mounting them on the Chi circle of a Huber 4 circle diffractometer. The angles were scanned in 1 degree intervals over a range of +/- 35 degrees. In these tests the resolution was about +/- 5 (mu)rad but the repeatability depended on angle and varied from 70 (mu)rad (one standard deviation) at large angles to 7 (mu)rad at small angles. This type of tilt sensor may be too slow (2-10 second settling time) as a primary angle encoder for a monochromator or diffractometer, but for a system run by stepping motors, they would prove quite useful as secondary angle encoders. Other models which have a narrower angular range would be useful in setting and tuning focusing mirrors. DOE

In a designed experiment, S is the white light source and is recorded as O(x0,y0). The LCLV is a light crystal light valve in a mixed field effect. The lens L1 forms the image I(x,y) on a CdS membrane of the light conducting layer of the light valve. When the voltage of the liquid crystal layer is greater than the threshold of the liquid crystal, a voltage image can be formed on the CdS membrane and the liquid crystal which corresponds to the input light image. THEORETICAL ASPECTS OF ELECTRON EMISSION HOLOGRAPHY
L. Fonda (Trieste Univ., Italy.) Nov. 1994 28 p
(DE95-614371; IC-94/342) Avail: CASI HC A03/MF A01 (US Sales Only)

A new surface structure determination approach, called either photoelectron or Auger electron holography depending on the process under consideration, to get three-dimensional images of the close vicinity of a given near-surface atom emitter, has recently been developed. The great advantage of this holographic method lies in the knowledge of the reference wave, a point which is not shared by structure determination

approaches using an external beam of particles, such as e.g. x-ray and neutron diffractions, where the reference wave is lost into some direction which is not observed, and the experimenter is therefore faced with the so-called 'phase problem.' DOE

TEMPORAL FEATURE EXTRACTION IN PHOTOREFRACTIVE RESONATORS Final Report

Dana Z. Anderson, Gan Zhou, and Germano Montemezzani 1 Dec. 1994 18 p

(Contract DAAL03-91-G-0312)

(AD-A292908; ARO-28592.4-PH) Avail: CASI HC A03/MF A01

A holographic optical system listens to an incoming signal and extracts the most common repetitive temporal features of that signal. An example might be to extract the features of Morse code, which consists of two tone lengths and two pause lengths. This optical system is self-organizing, in that very little a priori information is imbeded in the system to indicate what form the temporal signals take. The primary constraints imposed on the signal is: (1) finite bandwidth; (2) limited feature duration; and (3) rates of reoccurrence. The optical apparatus uses a photorefractively pumped multimode optical oscillator having a delay line in the feedback loop. The delay line serves to translate the temporal dimension into a spatial one, and it also builds into the system a notion of the direction of time. Temporal feature extraction takes place as a competitive interaction among sets of modes, which are termed chronomodes. Experiments illustrate the principles of such a system by extracting the two most probable temporal features from a signal imposed on a laser beam. DTIC

THE WIDE FIELD/PLANETARY CAMERA 2 (WFPC-2) MOLECULAR ADSORBER

Jack Barengoltz, Sonya Moore, David Soules, and Gerald Voecks 15 Jan. 1995 49 p

(Contract NAS7-1260; RTOP 485-15-00-03)

(NASA-CR-198866; JPL-Publ-94-001; NAS 1.26:198866) Avail: CASI HC A03/MF A01

A device has been developed at the Jet Propulsion Laboratory, California Institute of Technology, for the adsorption of contaminants inside a space instrument during flight. The molecular adsorber was developed for use on the Wide Field Planetary Camera 2, and it has been shown to perform at its design specifications in the WFPC-2. The basic principle of the molecular adsorber is a zeolite-coated ceramic honeycomb. The arrangement is efficient for adsorption and also provides the needed rigidity to retain the special zeolite coating during the launch vibrational environment. The adsorber, on other forms, is expected to be useful for all flight instruments sensitive to internal sources of contamination. Typically, some internal contamination is unavoidable. A common design solution is to increase the venting to the exterior. However, for truly sensitive instruments, the external contamination environment is more severe. The molecular adsorber acts as a one-way vent to solve this problem. Continued development is planned for this device. Author

NOVEL MASS SPECTROMETRIC INSTRUMENT FOR GASEOUS AND PARTICULATE CHARACTERIZATION AND MONITORING Final Report, Sep. 1992 - - Aug. 1994

M. J. Coggiola, C. H. Becker, and C. L. Witham Oct. 1994 62 p

(Contract DE-AC21-92MC-29116)

(DE95-000047; DOE/MC-29116/3956) Avail: CASI HC A04/MF A01

An instrument is being developed that will be capable of providing real-time (less than 1 minute), quantitative, chemical analysis of gaseous and particulate pollutants generated from DOE waste cleanup activities. The instrument can detect and identify volatile organic compounds, polynuclear aromatic hydrocarbons, heavy metals, and transuranic species released during waste cleanup. It consists of an isokinetic sampler operable up to 500 K and wide flow rate range, a high- to low-pressure transition and sampling region separating particles from vapors for separate analysis, two small mass spectrometers (one for organic analysis by field ionization and one for particulate analysis by thermal pyrolysis and electron-impact ionization), and a powerful PC for control/data acquisition. Initially, the instrument will used with the K-1435 Toxic Substances Control Act (TSCA) incinerator at K-25; other applications are also possible, e.g., vitrification monitoring, storage tank offgassing analysis, etc. It will be easily transportable. STABLE HIGH-POWER HARMONIC GYRO-AMPLIFIERS Final Report

N. C. Luhmann, Jr. 30 Sep. 1994 26 p

(Grant AF-AFOSR-0382-91)

(AD-A293697; AFOSR-95-0327TR) Avail: CASI HC A03/MF A01

The focus of our Tri-Service University Research Program in Vacuum Electronics has been on basic research issues associated with operating harmonic gyrotron devices as high-power, coherent millimeter-wave amplifiers. Substantial theoretical and experimental progress has been achieved. We introduced the marginal stability design (MSD) procedure for achieving stability in high-performance gyro-TWT's. We also concluded the initial tests of the high power, second-armonic TE21 gyro-TWT amplifier which is based on the MSD procedure and the novel concept that harmonic operation is capable of significantly increasing the output power because the start-oscillation beam current is much higher for the relatively weak harmonic interaction. Indeed, the second-harmonic gyro-TWT amplifier's unprecedented output power of 207 kW exceeded the previous record-level of 120 kW, which was produced by a first-harmonic gyro-TWT. Our amplifier yielded an efficiency of 13%, a saturated gain of 16 dB with a bandwidth of 2% and was stable for zero RF input power. DTIC

GLOBAL STABILIZATION OF NONLINEAR GYROSCOPIC SYSTEMS Ph.D. Thesis

Chih-Jian Wan 1994 191 p

Avail: Univ. Microfilms Order No. DA9423340

We concentrate on the problems of stability and stabilization of equilibrium points for certain nonlinear dynamical systems, primarily rigid body systems with gyroscopic effects. We analyze stability of the equilibrium points of these systems, and, in the presence of control inputs, we synthesize control laws that globally asymptotically stabilize these systems to the equilibrium points. The control law synthesis method developed here is based on the Hamilton-Jacobi-Bellman theorem which guarantees stability and also provides an optimality interpretation for the control law. In particular, we attempt to achieve both the objectives of stability and optimality for the nonlinear control system by finding solutions to the Hamilton-Jacobi-Bellman equation. It is shown that the performance index obtained is not prescribed a priori, rather, there is a relationship between the nonlinear system, the stabilizing control law and the Lyapunov function for the closed-loop system through the Hamilton-Jacobi-Bellman equation. These results are then specialized to nonlinear affine control systems, Jurdjevic-Quinn type systems and minimum phase system with relative degree (1,...,1). The dynamical systems considered in this dissertation are primarily gyroscopic systems which include, in general, nonlinear coupling, centrifugal forces and trigonometric functions in the equations of motion. These inherent nonlinearities can help stabilize the nonlinear system as shown in examples in which the interplay between dynamics and control plays an important role. Hence, we connect modern nonlinear control theory and classical optimal control theory in the framework of the Hamilton-Jacobi-Bellman theorem and apply this to several nonlinear gyroscopic systems. We show that by taking advantage of the inherent nonlinearities embedded in the nonlinear system, we derive elegant and powerful results which are useful for practical applications. Dissert. Abstr.

HIGH-RESOLUTION SUPERCONDUCTING X-RAY SPECTROMETERS WITH ALUMINUM TRAPPING LAYERS OF DIFFERENT THICKNESSES

C. A. Mears, S. E. Labov, L. H. Miller, M. Frank, H. Netel, F. Azgui, and A. T. Barfknecht Oct. 1994 6 p Presented at the Applied Superconductivity Conference, Boston, MA, 16-21 Oct. 1994

(Contract W-7405-eng-48)

(DE95-010253; UCRL-JC-119292; CONF-941013-35) Avail: CASI HC A02/MF A01

Superconducting tunnel junctions coupled to superconducting absorbers may be used as high-resolution, high-efficiency x-ray spectrometers. We have tested devices with niobium x-ray absorbing layers coupled to aluminum layers that serve as quasiparticle traps. We present a study of device

performance as a function of thickness of the trapping layers. We measured the best energy resolution using a device with a high-quality barrier and 200 nm-thick trapping layers on both sides of the tunnel barrier. This energy resolution was 36 eV full width at half maximum at 6 keV, about 4 times better than that obtainable using semiconductor ionization detectors.

J. Svedin, U. Dahlgren, H. Johansson, O. J. Hagel, and H. Zirath Oct. 1994 32 p In SWAHILI; Test in SWEDISH; summary in ENGLISH Prepared in cooperation with Chalmers Univ. and the Industrial Microelectronics Center
(PB95-210399; FOA-R-94-00007-3.2-SE) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report gives a summary of activities and results attained in the project during the project phase MMS2.1. It is mainly intended for the sponsors of the project, and for those who are familiar with the project's activities. A number of millimeter wave (35 and 94 GHz) 1X4 integrated receiver arrays aimed at anti-collision radar and target seeker applications have been designed, manufactured and characterized. The circuits, which are patterned on a BCB substrate using a uniplanar hybrid technology (MMS1.2b) presented earlier, comprise integrated microstrip patch antennas, resistive InP HEMT mixers, and microstrip distribution, matching and diplexer networks. To facilitate an accurate characterization using our probe station, circuit breakouts including via holes have been manufactured. At 35 GHz we have measured antenna diagrams for separate receivers in an array, conversion loss, various bandwidths and linearity for a mixer breakout, and s-parameters for some of the passive microstrip circuit breakouts. A performance comparison with the GaAs based HEMT mixer presented earlier has also been carried out.

LASER TRACKER 3: SANDIA NATIONAL LABORATORIES' THIRD GENERATION LASER TRACKING SYSTEM
D. L. Patrick 1995 5 p Presented at the SPIE International Symposium on Aerospace/Defense Sensing and Dual-use Photonics, Orlando, FL, 17-21 Apr. 1995
(Contract DE-AC04-94AL-85000)
(DE95-008525; SAND-95-0472C; CONF-950472-2) Avail: CASI HC A01/MF A01

At Sandia Labs' Coyote Canyon Test Complex, it became necessary to develop a precision single station solution to provide time space position information (tspi) when tracking airborne test vehicles. Sandia's first laser tracker came on line in 1968, replacing the fixed camera technique for producing trajectory data. This system shortened data reduction time from weeks to minutes. Laser Tracker 2 began operations in 1982, replacing the original tracker. It incorporated improved optics and electronics, with the addition of a microprocessor-based real-time control (rtc) system within the main servo loop. The rtc added trajectory prediction with the loss of adequate tracking signal and automatic control of laser beam divergence according to target range. Laser Tracker 3, an even more advanced version of the systems, came on line in 1990. Unlike LT 2, which is mounted in a trailer and must by moved by a tractor, LT 3 is mounted on its own four-wheel drive carrier. This allows the system to be used at even the most remote locations. It also incorporated improved optics and electronics with the addition of absolute ranging, acquisition on the fly, and automatic transition from manual Joystick tracking to laser tracking for aircraft tests. LT 3 provides a unique state of the art tracking capability for missile, rocket sled, aircraft, submunition, and parachute testing. Used in conjunction with LT 2, the systems together can provide either simultaneous or extended range tracking. Mobility, accuracy, reliability, and cost effectiveness enable these systems to support a variety of testing at Department of Energy and Department of Defense ranges.

Kilcoyne et al 1995 12 p Presented at the SPIE 1995: SPIE Conference on Optics, Electro-Optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract DE-AC04-94AL-85000)

(DE95-008526; SAND-95-0482C; CONF-950226-26) Avail: CASI HC A03/MF A01

The gain-dependent polarization properties of vertical-cavity surface emitting lasers and methods for polarization control and modulation are discussed. The partitioning of power between the two orthogonal eigen polarizations is shown to depend upon the relative spectral alignment of the nondegenerate polarization cavity resonances with the laser gain spectrum. A dominant polarization can thus be maintained by employing a blue-shifted offset of the peak laser gain relative to the cavity resonance wavelength. Alternatively, the polarization can be controlled through use of anisotropic transverse cavity geometries. The orthogonal eigen polarizations are also shown to enable polarization modulation. By exploiting polarization switching transitions in cruciform lasers, polarization modulation of the fundamental mode up to 50 MHz is demonstrated. At lower modulation frequencies, complementary digital polarized output or frequency doubling of the polarized output is obtained. Control and manipulation of vertical-cavity laser polarization may prove valuable for present and future applications. DOE

OPTIMUM TRUNCATION OF A GAUSSIAN BEAM FOR PROPAGATION THROUGH ATMOSPHERIC TURBULENCE
H. T. Yura 15 Nov. 1994 20 p
(Contract F04701-93-C-0094)
(AD-A291156; TR-94(4925)-2; SMC-TR-95-7) Avail: CASI HC A03/MF A01

We consider the mean on-axis far-field (or focal-plane) irradiance of a Gaussian beam truncated by a circular aperture in the presence of atmospheric turbulence. In the absence of turbulence, we present an accurate analytic approximation for the irradiance distribution that is valid within the main central lobe of the beam. Based on this approximation, we then obtain the mean on-axis far-field irradiance and corresponding turbulence Strehl ratio for the truncated Gaussian beam. By maximizing the on-axis irradiance, we obtain the optimum ratio of the beam diameter to the aperture diameter in the presence of turbulence and present results for the corresponding maximum on-axis irradiance as a function of the strength of turbulence. In particular, for D/r sub 0 greater than 1, where D is the aperture diameter, and r sub 0 is Fried's coherence length, optimum truncation of a Gaussian beam and uniform illumination of a circular aperture (where the same total power is uniformly distributed over the aperture) result in the same on-axis irradiance in the presence of uncompensated turbulence. DTIC

EXTENDED TUNING RANGE SEMICONDUCTOR LASERS WITH SAMPLED GRATINGS Ph.D. Thesis
Vijaysekhar Jayaraman 1994 211 p
Avail: Univ. Microfilms Order No. DA9423867

Prior to 1991, the most advanced tunable semiconductor laser was the 'Distributed Bragg Reflector' or DBR laser. The tuning limitation in DBR lasers is a cavity design which constrains the fractional wavelength tuning Delta lambda/lambda to be no more than the achievable refractive index change Delta mu/mu in a semiconductor waveguide. The maximum index shift is approximately 0.7 percent. As a result, the best DBR lasers have a tuning range of 10 nanometers (nm) around their nominal operating wavelength of 1.5 microns. This dissertation describes a new type of tunable semiconductor laser, which can have a tuning range Delta lambda/lambda which is much larger than Delta mu/mu. This new laser relies on reflection gratings like DBR lasers, and therefore relies on a similar fabrication technology. In contrast to DBR lasers, however, the 'sampled grating' DBR of this dissertation uses gratings which are periodically turned on and off, generating a reflection spectrum with periodic maxima. This spectrum allows tunability over much wider ranges than the single reflection maximum associated with DBR mirrors. The first chapter of this dissertation is devoted to describing the history of tunable semiconductor lasers. The next two chapters describe the theory of sampled gratings and the tuning properties of lasers employing them. The following two chapters describe fabrication and device results. In particular, in Chapter 5, we describe tunable lasers with 10 mW output power, tuning ranges over 70 nm, and single-frequency operation with very large suppression of spurious laser cavity modes. Chapter 6 summarizes, and concludes with some suggestions for improving device performance and exploring new geometries. Dissert. Abstr.

ELECTRON-OPTICAL NONLINEAR INTERACTION IN ASYMMETRIC QUANTUM-WELL LASER HETEROSTRUCTURES
V. K. Kononenko, A. A. Afonenko (Belarussian State Univ., Minsk, Belarus.), and I. S. Manak (Belarussian State Univ., Minsk, Belarus.) Sep. 1994 10 p Sponsored by Fundamental Research Foundation of the Republic of Belarus
(DE95-613443; IC-94/284) Avail: CASI HC A02/MF A01 (US Sales Only)

The effects of nonlinear electron-optical interaction between two quantum wells in the active region of low-dimensional lasers with inhomogeneous excitation are discussed. The conditions for realizing bistable behaviour of optical output and self-sustained pulsations of radiation at two optical wavelengths are determined. The influence of current carrier leakage on the hard regime of lasing is considered. The synchronization effect of coupled well modulation of injection on pulse generation has been predicted. Analysis based on rate equations has been performed for the GaAs - Al(x)Ga(1-x)As system. DOE

METHOD FOR LASER-ASSISTED SILICON ETCHING USING HALOCARBON AMBIENTS Patent
Stephen D. Russell, inventor (to Navy), Douglas A. Sexton, inventor (to Navy), and Richard J. Orazi, inventor (to Navy) 31 Jan. 1995 23 p Filed 29 Mar. 1990
(AD-D017426; US-Patent-5,385,633; US-Patent-Appl-SN-501707; US-Patent-Class-156-693) Avail: US Patent and Trademark Office

An etching process allows a selective single-step patterning of silicon devices in a noncorrosive environment. The etching of silicon relies on a maskless laser-assisted technique in a gaseous halocarbon ambient, such as the gaseous chlorofluorocarbons, dichlorodifluoromethane and chloropentafluoroethane. Laser-assisted photothermal chemical etching reactions on silicon occur in these ambients when the incident fluence from an excimer laser at 248 nm exceeds the melt threshold (approximately 0.75 J/sq cm). When incident fluence exceeds the ablation threshold (approximately 2.2 J/sq cm) an undesirable increased surface roughness is observed. Etch rates as large as approximately 15 angstroms per pulse are attained within predetermined processing windows. This provides a means for thin membrane formation in silicon, rapid etches and processing of packaged devices or partially fabricated dies. The reduction in processing steps as compared to conventional wet chemical etches provides improvements in yield, reliability and cost. DTIC

TV-VI SEMICONDUCTOR QUANTUM WELL LASERS, PHYSICS AND ENGINEERING Ph.D. Thesis
Majed Fouad Khodr 1994 253 p
Avail: Univ. Microfilms Order No. DA9422557

In this work, a theoretical model that calculates the gain-current density relationship for IV-VI semiconductor quantum well lasers was developed. The model, based on Kane's two band model, solves for the anisotropy in the constant energy surfaces and for the strong nonparabolicity of the bands. The system investigated was the EuSePbSe(0.78)Te(0.22) quantum well structure at 77 K. The nonparabolicity of the bands in the growth direction was found to shift the energy levels in the PbSe(0.78)Te(0.22)

quantum well to lower energies as compared to a quantum well with parabolic bands. Nonparabolicity of the bands also resulted in an energy dependent density of states in the junction plane of the structure. These two effects cause the gain-current density relation for the parabolic system to be altered. The single quantum well (SQW) design was optimized by investigating three quantum well structures: the multiple quantum well (MQW), the modified multiple quantum well (MMQW) and the separate confinement heterostructure-single quantum well (SCH-SQW) structures. The effects of nonparabolicity on the confinement factor and threshold current values were also calculated. Nonparabolicity lowers the confinement factor values and thus, the modal gain. Also, it increases the threshold current values for short cavity lasers. For moderate and long cavity lasers, these effects are negligible. Studies were performed on BaF2 films because of their importance as intermediate layers that lattice match the IV-VI semiconductor devices to silicon. BaF2 films were grown in a vacuum system with a base pressure of 10(exp -6) Torr on Si(111) substrates at four substrate temperatures: room temperature, 250 C, 450 C and 650 C. The fluoride films were characterized using ellipsometry, X-ray diffraction, scanning electron microscopy (SEM) and capacitance versus voltage techniques. At a growth temperature of 650 C, the BaF2 films were epitaxial with a (111) preferred growth direction. At this temperature, the surface was partially smooth with some cracking apparent. Prolonged heating of a chemically uncleaned substrate before deposition resulted in smooth and crack-free CaF2 films. The electrical properties of the films correlated with the thermal history of the sample rather than with the crystalline quality.

ANALYSIS OF PLANAR LASER-INDUCED FLUORESCENCE IMAGES OBTAINED DURING SHAKEDOWN TESTING OF THE AEDC IMPULSE FACILITY Final Report, Oct. 1993 - Sep. 1994
W. M. Ruyten, W. D. Williams, and F. L. Heltsley Mar. 1995 62 p
(AD-A293237; AEDC-TR-94-14) Avail: CASI HC A04/MF A01

Following a proof-of-principle demonstration of Planar Laser-Induced Fluorescence (PLIF) in the AEDC Impulse Facility in FY93, a set of four PLIF images was obtained during FY94 runs of the facility. The images were obtained away from the nose region of a spherically blunt cone, using excitation of nitric oxide in the flow. Two laser sheet geometries were employed and two excitation wavelengths were used. A procedure was developed whereby calibration images allow the remapping of the PLIF images to test article coordinates. Using this technique, it was shown that the bow shock positions determined by PLIF agree well with the shock positions measured using schlieren photography. More importantly, the set of PLIF images constitutes an initial database against which Computational Fluid Dynamics calculations of high enthalpy flows can be compared. Initial results of such a comparison, obtained through Computational Flow Imaging, are reported. Recommendations are given for future PLIF applications at the Impulse Facility. DTIC

FREE ELECTRON LASER AS ENERGY DRIVER FOR INERTIAL CONFINEMENT FUSION
E. L. Saldin, E. A. Shnejdmiller, Yu. N. Ulyanov, V. P. Sarantsev, and M. V. Yurkov 1994 42 p
(DE95-614252; JINR-E-9-94-237) Avail: CASI HC A03/MF A01 (US Sales Only)

A FEL based energy driver for Inertial Confinement Fusion (ICF) is proposed. The key element of the scheme is free electron laser system. Novel technical solutions reveal a possibility to construct the FEL system operating at radiation wavelength lambda = 0.5 micro m and providing flash energy E = 1 MJ and brightness 4 x 10(exp 22) W/sq cm.sr within steering pulse duration 0.1-2 ns. Total energy efficiency of the proposed ICF energy driver is about of 11% and repetition rate is 40 Hz. Dimensions of such an ICF driver are comparable with those of heavy-ion ICF driver, while the problem of technical realization seems to be more realistic. It is shown that the FEL based ICF energy driver may be constructed at the present level of accelerator technique R&D. DOE

SPOTSIZE MEASUREMENTS OF A FOCUSED CW Nd: YAG LASER
Marcelino Essien, L. Paul Schanwald, and Phillip W. Fuerschbach 1995 7 p Presented at the SPIE 1995 Conference: SPIE Conference on Optics, Electro-optics, and Laser Application in Science, Engineering and Medicine, San Jose, CA, 5-10 Feb. 1995
(Contract DE-AC04-94AL-85000)
(DE95-007746; SAND-94-0252C; CONF-950226-20) Avail: CASI HC A02/MF A01

The minimum spotsize, beam quality or M(sup 2), and Strehl ratio of a focused laser beam provide different measures of the performance of the laser/optic system. Focusing lenses typically used to provide irradiances sufficient to cause melting and/or vaporization of metals or ceramics typically exhibit considerable spherical aberration, and thus limit the minimum spotsize attainable for a given lens at a specific laser power. The purpose of this work is to quantify the increase in the minimum spotsize and decrease in Strehl ratio of a focused materials processing CW Nd:YAG laser caused by laser cavity heating and spherical aberration introduced by the focusing lens. Minimum spotsize was determined by making several measurements of spotsize along the propagation direction using a scanning aperture system, and fitting the data to the laser propagation equation. These measurements were performed for 6 plano-convex lenses of different focal lengths, using laser powers ranging from 500 to 1500 watts. A nonlinear variation of spotsize with laser power and with focal length was observed for the lenses and power levels tested. DOE

EXPERIMENTAL INVESTIGATION OF OPTICAL NONLINEARITIES IN CONJUGATED POLYMERS Annual Report, 1 Sep. 1993 - 31 Aug. 1994
George Stegeman 31 Aug. 1994 6 p
(Contract F49620-93-1-0554)
(AD-A288353; AFOSR-94-0093TR) Avail: CASI HC A02/MF A01

The nonlinear optics of sublimated films of 2-dimensional conjugated planar molecules has been investigated by third harmonic generation. Two were planar phthalocyanines, metal-free and copper substituted, and the third was an asymmetric (non-planar) phthalocyanine (subphthalocyanine), employed as a precursors in the synthesis of certain phtalocyanines. A very rich spectrum has been observed in each case and the analysis is currently underway. In the future this work will be expanded to include other materials. DTIC

DESIGN CONSIDERATIONS FOR A DENSITY-CHANNEL-GUIDED LASER WAKE-FIELD ACCELERATOR Interim Report
Jonathan Krall and Arie Zigler 14 Apr. 1995 22 p Prepared in cooperation with Hebrew Univ. of Jerusalem, Rehovot, Israel
(AD-A292876; NRL/MR/6790-95-7651) Avail: CASI HC A03/MF A01

A self-modulated laser wake-field accelerator configuration in which the laser pulse is optically guided by a plasma density channel is considered. Preliminary experiments on the generation of a plasma channel by a slow capillary discharge are described. It is shown that homogeneous channels with length L sub channel much greater than lambda p can be produced, where lambda sub p is the plasma wavelength. Key issues are addressed, including phase detuning between the accelerated electron bunch and the wake field, beam-plasma and laser-plasma instabilities, and the effect of density variations that might occur over the length of the plasma channel. Numerical simulations, using present experimental parameters, show accelerating gradients in excess of 50 GV/m. DTIC

A 1.94 MICROMETER LASER APPARATUS, SYSTEM AND METHOD USING A THULIUM-DOPED YTTRIUM-LITHIUM-FLUORIDE LASER CRYSTAL PUMPED WITH A DIODE LASER Patent
Leon Esterowitz, inventor (to Navy) and Robert C. Stoneman, inventor (to Navy) 10 Jan. 1995 8 p Filed 28 Jan. 1993
(AD-D017435; US-Patent-5,381,433; US-Patent-Appl-SN-010253; US-Patent-Class-372-41) Avail: US Patent and Trademark Office

A laser apparatus, system and method include a laser crystal formed of thulium-doped yttrium-lithium-fluoride, and a laser diode arranged in proximity to the laser crystal. The laser diode is capable of emitting a first laser light which is suitable for use as a pump beam for causing lasing to occur in the laser crystal. In response to the first laser light from the laser diode, the laser crystal emits a second laser light at a wavelength which

is relatively highly-absorbed by organic tissue and/or water. The second laser light is therefore well-suited to medical applications, for example, and can be used to irradiate organic tissue for medical treatment. DTIC

(AD-A289737; NAIC-IS(RS)T-0703-94) Avail: CASI HC A03/MF A01

Chemical laser is characteristically energized by an exoergic chemical reaction which produces the necessary population inversion of lasing species. Based on the enormous chemical energy deposit, several kinds of chemical laser now deliver the cw power outputs of megawatt magnitude, far higher than any other lasers. Accordingly, along with the improvement of gas medium homogeneity and mode-selectivity of the optical cavity chemical laser has also attained high beam quality of a near diffraction-limited divergence angle. Recent efforts in developing new chemical laser have focused on the short wavelength chemical laser system, e.g. from the early DF (iota = 3.8 micrometer) and HF (lambda = 2.7 micrometer) to late O2(1) Delta)-1 (lambda = 1.315 micrometer) and HF overtone transition laser (approx. 13 micrometer). At present the community of chemical physics are much interested in the visible chemical laser which may be realized by stimulated emission of an electronic excited state. DTIC

ION-ASSISTED PULSED LASER DEPOSITION OF AMORPHOUS TETRAHEDRAL-COORDINATED CARBON FILMS
T. A. Friedmann, D. R. Tallant, J. P. Sullivan, M. P. Siegal, and R. L. Simpson 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC04-94AL-85000)
(DE95-010861; SAND-95-0166C; CONF-941144-143) Avail: CASI HC A02/MF A01

A parametric study has been performed of amorphous tetrahedral carbon (a-tC) films produced by ion-assisted pulsed laser deposition (IAPLD). The ion voltage, current density, and feed gas composition (nitrogen in argon) have been varied. The resultant films were characterized by thickness, residual stress, Raman spectroscopy, and electrical resistivity. The Raman spectra have been fit to two gaussian peaks, the so called graphitic (G) peak and the disorder (D) peak. It has been found that the magnitude of the D peak and the residual compressive stress are inversely correlated. At low beam voltages and currents, the magnitude of the D peak is low, increasing as the ion beam voltage and current are raised. The ion beam voltage has the most dramatic effect on the magnitude of the D peak. At low voltages (200-500 V) the magnitude of the D peak is greater for ion beams with high percentages of nitrogen possibly indicative of C-N bonding in the films. At higher voltages (500-1500 V) the D peak intensity is less sensitive to the nitrogen content of the beam. DOE

A COMPACT AND EFFICIENT VIOLET LASER SOURCE Final Report, 15 Jun. - 15 Dec. 1994
D. C. Gerstenberger Feb. 1995 15 p
(Contract F49620-94-C-0036)
(AD-A292782) Avail: CASI HC A03/MF A01

The purpose of this Phase 1 program was to investigate a compact and efficient laser source in the 430nm violet spectral range using frequency-doubling of a cw single-mode AlGaAs diode laser in an external resonant doubler constructed of potassium niobate. The primary objective of the Phase 1 program was to develop and evaluate a novel monolithic frequency-doubler design. Another goal was to eliminate the need for an optical isolator. Several monolithic potassium niobate resonant doublers were constructed and tested with Fabry-Perot (F-P) and distributed-Bragg-reflector (DBR) diode lasers. Approximately 9mW of cw 430nm violet light was generated with the best doubler. The DBR laser was found to be more than 100 times less sensitive to feedback than the F-P diode laser, but neither laser provided stable frequency-doubled output in Phase 1 experiments. DTIC

ULTRAVIOLET AND VISIBLE LASERS: RARE EARTH-DOPED WAVEGUIDE DEVICES AND NON-LINEAR OPTICAL EXTRACTION TECHNIQUES Final Report, 1 Dec. 1991 - 30 Nov. 1994
J. G. Eden Dec. 1994 37 p
(Contract F49620-92-J-0089)
(AD-A293976; AFOSR-95-0321TR) Avail: CASI HC A03/MF A01

Over the past three years, AFOSR has supported a combined experiment at the University of Illinois that has focused on the demonstration and development of new coherent sources operating in the ultraviolet and short wavelength portion of the visible (green to violet). This research effort has two thrusts. Emphasis is being placed on the demonstration of fiber and planar waveguide lasers based upon upconversion processes in rare earth doped glasses. These devices have several attractive features for applications in communications, reprographics and medicine (in particular), including: (1) wide tunability (several nm); (2) broad absorption spectra suitable for diode laser pumping; (3) overall efficiencies exceeding 10% despite the required absorption of at least two pump photons; (4) pump-gain

medium interaction lengths not normally available with bulk crystals; (5) the ability to integrate planar waveguide glass-based lasers with other devices such as EO-modulators and laser diodes; and (6) multiple wavelengths and high quantum efficiencies (greater than 50%). DTIC

BASIC STUDY OF THE PUMPING OF A GAMMA-RAY LASER Annual Report, 15 Mar. 1994 - 14 Mar. 1995

C. B. Collins and J. J. Carroll 15 Apr. 1995 116 p

(Contract N00014-93-K-2005)

(AD-A293561; GRL/9501) Avail: CASI HC A06/MF A02

The most productive approaches to the problem of the gamma ray laser have focused upon upconversion techniques in which metastable nuclei are pumped with long wavelength radiation. At the nuclear level the storage of energy can approach tera-Joules (10(exp 12)J) per liter for thousands of years. However, any plan to use such a resource for a gamma ray laser poses problems of a broad interdisciplinary nature requiring the fusion of concepts taken from relatively unrelated fields of physics. Our research group has described several means through which this energy might be coupled to radiation field with cross sections for stimulated emission that could reach 10(exp -17) sq cm. Such a stimulated release could lead to output powers as great as 3 x 102 Watts/liter. Since 1978 we have pursued an approach for the upconversion of longer wavelength radiation incident upon isomeric nuclear populations that can avoid many of the difficulties encountered with traditional concepts of single-photon pumping. Experiments have confirmed the general theory and have indicated that a gamma-ray laser is feasible if the right combination of energy levels and branching ratios exists in some real material. Of the 1,886 distinguishable nuclear materials, the present state-of-the-art has been adequate to identify 29 first-class candidates, but further evaluation cannot proceed without remeasurements of nuclear. A laser-grade database of nuclear properties does not yet exist but the techniques for constructing one have been developed and utilize under this contract. DTIC

PRIME POWER FOR SHIPBOARD HIGH-AVERAGE POWER FELs M.S. Thesis

Robert A. Lyon, Jr. Dec. 1994 97 p Limited Reproducibility: Document partially illegible

(AD-A293718) Avail: CASI HC A05/MF A02

High-power free electron lasers (FEL's), capable of deployment aboard naval combatants, would place a unique and significant demand upon the ship's electrical distribution system. A shipboard FEL must be power efficient, relatively compact, and present a minimum radiation hazard to nearby personnel. The feasibility of deploying an FEL aboard a ship is analyzed from a power system perspective. To produce 1 MW of laser power, it is determined that 6.6 MW of high-voltage dc power is required to drive the FEL when superconductor accelerator technology is employed and 9 MW is required when conventional room temperature accelerator technology is used. The required prime power electrical distribution is easily compatible with the gas turbine engineering plants of modern surface combatants. This distribution will add 22 tons to the ship's displacement and require 22 m3 of the ship's volume to implement. Simulation results show that the FEL would require an undulator with only 16 periods to produce 1 MW for the electron beam parameters developed during the power analysis. This FEL exhibits a large tolerance to electron beam quality. From a power analysis viewpoint, FEL's may become a competitive technology for a prospective naval laser weapon. DTIC

CARRIER DYNAMICS AND OPTICAL PROPERTIES OF GaAs- AND InP-BASED STRAINED QUANTUM WELL LASERS Ph.D. Thesis

Lawrence John Davis, IV 1994 161 p

Avail: Univ. Microfilms Order No. DA9423171

As material quality and processing techniques continue to improve over the years, the performance of optoelectronic devices using multiple quantum wells has reached the point where intrinsic material characteristics, such as carrier transport, recombination lifetime, etc., are expected to be important issues. These intrinsic characteristics have been investigated with respect to laser and modulator structures. Carrier transport was investigated in AlGaAs/GaAs and InGaAs/InAlAs modulator structures using an all-optical time-of-flight technique, allowing temporal resolution of approximately 1 ps. The observed fast transport times can only be explained by a field-dependent carrier emission out of the quantum well, after which transport through the continuum states can occur. The carrier relaxation processes to the quantum well, including the carrier diffusion, capture into the quantum well and relaxation in the well, have been studied. If the electron-hole (e-h) recombination time by stimulated emission for a laser at high injection approaches these relaxation times, the carrier distribution in the quantum well can be 'hot' and is not described by a quasi Fermi distribution. This creates serious limitations for the laser performance by introducing gain-compression enhanced Auger rates and other hot-carrier related effects. These Auger recombination rates have been measured in compressively strained In(x)Ga(1-x)As/InGaAsP/InP quantum wells for the first time. The Auger recombination rates were derived from the measured turn-on delay times during large-signal modulation of single mode lasers. A new device concept has been demonstrated to overcome these intrinsic processes. In this device, termed the tunneling injection quantum well laser, carriers are transported to the active lasing subband by resonant and sequential tunneling. Record performance compared to other single quantum well lasers has been demonstrated in terms of differential gain and modulation bandwidth, showing the potential for this new device. Dissert. Abstr.

ENHANCED BRIGHTNESS X-RAY LASERS

A. S. Wan, R. C. Cauble, L. B. DaSilva, J. C. Moreno, and J. Nilsen Sep. 1994 6 p Presented at the ECLIM 23: Laser Interaction With Matter, Oxford (England), 19-23 Sep. 1994

(Contract W-7405-eng-48)

(DE95-010735; UCRL-JC-116841; CONF-9409226-6) Avail: CASI HC A02/MF A01

We are developing short-pulsed, enhanced-brightness, and coherent x-ray lasers (XRL's) for applications in areas such as plasma imaging. In a traveling wave pump setup the optical laser creating the XRL plasma sweeps along the lasant axis at the same speed as the x-rays. This technique becomes increasingly important as the target length increases and the gain duration shortens. An order of magnitude increase in output energy was measured with vs without traveling wave pump. Using multiple pulse techniques and multilayer mirrors to inject the output of one pulse back into the plasma formed by a later pulse we have begun to develop the x-ray analog of a multi-pass amplifier. The use of multiple pulses separated by as much as 1.6 ns reduces multilayer mirror damage. This injection technique is demonstrated by imaging the near-field emission profiles of the XRL. The addition of multilayer beamsplitter will allow us to effectively produce a soft XRL cavity. DOE

SANDIA NATIONAL LAB'S PRECISION LASER TRACKING SYSTEMS

D. Patrick 1995 5 p Presented at the Test Facility Working Group Conference, Las Vegas, NV, 12-16 Jun. 1995

(Contract DE-AC04-94AL-85000)

(DE95-009837; SAND-95-0670C; CONF-9506174-1) Avail: CASI HC A01/MF A01

Sandia Labs' mobile tracking systems have only one moving part. The double gimballed 18 inch diameter beryllium mirror is capable of constant tracking velocities up to 5 rads/sec in both axes, and accelerations to 150 rads/sec(exp 2) in both axes. Orthogonality is less than 10 microradians. The mirror directs the 488 and 514 nm wavelength CW laser beams to adhesive-backed reflective material applied to the test unit. The mirror catches the return beam and visual image, directing the visual image to three camera bays, and the return beam to an image dissector behind an 80 inch gathering telescope. The image dissector or image position sensor is a photomultiplier with amplifying drift tube and electron aperture and its associated electronics. During the test, the image dissector scan senses the change in position of the reflective material and produces signals to operate the azimuth and elevation torque motors in the gimbal assembly. With the help of 1 1/8 in. diameter azimuth and elevation galvonometer steering mirrors in the optical path, the laser beam is kept on the target at extremely high velocities. To maintain a constant return signal strength, the outgoing beam is run through a microprocessor controlled beam focusing telescope. DOE

Results from both a regeneratively-initiated and self-initiated, mode-locked Cr:YAG laser which is tunable from 1.51 to 1.53 micro m are reported. One hundred and twenty femtosecond, nearly transform-limited pulses have been generated with peak output powers of 45 kW. The stable, high peak power pulses and room temperature operation of this laser make it a very suitable alternative to the cumbersome, cryogenic mode-locked NaCl laser commonly used in both narrow bandgap semiconductor and optical communications research. THE DEVELOPMENT OF A PULSED LASER IMAGING SYSTEM FOR NATURAL GAS LEAK DETECTION Abstract Only
Thomas J. Kulp 1995 2 p Presented at the Natural Gas Research, Development and Demonstration Contractors Review Meeting, Baton Rouge, LA, 4-6 Apr. 1995
(Contract DE-AC04-94AL-85000)
(DE95-011407; SAND-95-8561A; CONF-950494) Avail: CASI HC A01/MF A01

The detection of gas leaks represents a critical operation performed regularly by the gas industry to maintain the integrity and safety of its vast network of piping, both above and below the ground. We are developing a technology that allows the real-time imaging of gas plumes in a television format. Termed backscatter absorption gas imaging (BAGI), the technique operates by illuminating a scene with infrared laser radiation having a wavelength that is absorbed by the gas to be detected (in this case, methane). Backscattered laser radiation is used to create a video image of the scene. If a leak of the target gas is present in the field-of-view of the camera, it attenuates a portion of the backscatter and creates a dark cloud in the video picture. The specific purpose of this project is to investigate a new method of accomplishing BAGI using a pulsed laser source. The pulsed laser imager under development in this project is expected to have a range (greater than or equal to 40 m) and sensitivity (less than 10 ppm-m) that will surpass the respective attributes of a scanned continuous wave laser imager. The pulsed system will operate by flooding (rather than scanning) the imaged scene with pulses of laser radiation. Imaging will be accomplished using a focal-plane array camera that operates in a snapshot format. The higher power of the pulsed laser source and the more effective collection optics of the focal-plane array-based receiver will allow the performance enhancements to be achieved. DOE

LOW VIBRATION POLYMERIC COMPOSITE ENGINE Patent
David P. Guimond, inventor (to Navy) and Rolf K. Muench, inventor (to Navy) 6 Dec. 1994 6 p Filed 28 Sep. 1993
(AD-D017332; US-Patent-5-370,087; US-Patent-Appl-SN-127546; US-Patent-Class-123-546) Avail: US Patent and Trademark Office

An internal combustion engine is constructed with metallic parts in its regions which are subjected to high stress (temperature, pressure) during combustion and polymeric materials in its regions which are subjected to relatively lower stresses. The integrated construction helps realize increased power densities and reductions on engine noise without compromising engine performance. V-configuration Diesel engines particularly benefit from this construction. DTIC

COUPLING STUD ASSEMBLY Patent
Gus F. Plangetis, inventor (to Navy) 29 Nov. 1994 12 p Filed 24 Sep. 1993
(AD-D017335; US-Patent-5,368,344; US-Patent-Appl-SN-125712; US-Patent-Class-285-412) Avail: US Patent and Trademark Office

A coupling stud assembly for coupling together a pair of flanges is discussed. A stud having a tapered surface is inserted into respective overlapping through-holes provided in the flanges so that a space is defined between the stud and inner walls of the holes. A wedge is fitted into the space and is pressed by a wedge spacer so as to tighten contact between the stud and the inner walls of the through holes. Nuts are provided on threaded ends of the stud to securely couple the flanges together. This arrangement provides a tight, vibration-free coupling between the flanges. DTIC

GEAR PUMP WITH REDUCED FLUID-BORNE NOISE Patent
John W. Henry, inventor (to Navy), William F. Flickinger, inventor (to Navy), Joseph F. Dolinar, Jr., inventor (to Navy), Francisco A. Rodriguez, inventor (to Navy), and James W. Smith, inventor (to Navy) 1 Nov. 1994 9 p Filed 30 Sep. 1993
(AD-D017362; US-Patent-5,360,325; US-Patent-Appl-SN-129501; US-Patent-Class-418-126) Avail: US Patent and Trademark Office

A crescent internal gear pump achieves greatly improved sealing against counter flow of fluid and greatly reduced noise by increase of the number of teeth of each of the ring and pinion gears which form discrete volumes of pumped fluid against a crescent-shaped member or insert. Reduction of the size of the teeth ring and pinion gears allows an increase in the angular extent of the crescent-shaped insert in order to increase the number of discrete volumes to be increased to a minimum of nineteen for each of the ring and pinion gears. The reduction in noise is accompanied by an increase in the fundamental frequency of the remaining noise, which can be more readily attenuated by acoustic filtering and isolation. Perfecting features of the invention include shaping of the crescent shaped member

to equalize the number of discrete volumes formed by each of the ring and pinion gears and shaping the teeth of the pinion gear to equalize the volumes of the discrete volumes formed by each gear. DTIC

FAST-ACTING VALVE FOR PROJECTIVE LAUNCHING SYSTEMS Patent
Nicholas Bitsakis, inventor (to Navy) 27 Dec. 1994 10 p Filed 20 Dec. 1993
(AD-D017357; US-Patent-5,375,502; US-Patent-Appl-SN-169277; US-Patent-Class-891-810) Avail: US Patent and Trademark Office

A fast acting valve for use in a stored energy projectile launching system. The valve has an inlet port for connection to a storage energy device, an outlet port for connection to a launching tube and an intermediate chamber. The interior of the valve seat communicates with one of the ports through a plurality of apertures that permit liquid to transfer between the ports. A cylindrical valve lies inside the cylindrical valve seat and sealingly, slidingly engages the interior of the cylindrical valve seat. A microprocessor-based control system provides a controlled velocity profile transfer of the valve between a first position in which the valve seals the ports and a second position in which the valve clears the ports. DTIC

SPEED CONTROL OF AN ELASTIC TWO-MASS SYSTEM: OPTIMIZATION AND SYSTEMS THEORY
C. G. Baril and J. Galic 1994 37 p Sponsored by Swedish National Board for Industrial and Technical Development
(PB95-212106; TRITA-MAT-1994-29) Avail: CASI HC A03/MF A01

The speed control problem of an elastic two-mass system is studied in this work. This simple and basic system is often found in mechanical devices where a load inertia is driven by an electrical motor through an elastic coupling. Different linear controllers are checked and the applicability of each of them is established. We show some frequency domain constraints that must be satisfied by the controller in order to avoid low damped oscillations. These constraints are very difficult to satisfy for systems where the load inertia is small compared with the motor inertia. For this case we also show that with a minimum phase controller the peak shaft torque will be considerably high when a disturbance is applied on the load side. We finally present a cascaded linear controller, where the measured signals are both the motor speed and the shaft torque, or alternatively the motor speed and the load speed. In the first case the shaft torque measurement is used to estimate the load speed. This simple controller is able to damp the oscillations and to reduce the maximum shaft torque. NTIS

N95-30716 Department of the Navy, Washington, DC.
SMART MATERIAL JOINT BAND Patent
Michael A. Tucchio, inventor (to Navy), Robert A. Stoodt, inventor (to Navy), and Robert A. Livsey, inventor (to Navy) 22 Nov. 1994 6 p Filed 30 Dec. 1993
(AD-D017374; US-Patent-5,366,254; US-Patent-Appl-SN-176373; US-Patent-Class-285-23) Avail: US Patent and Trademark Office

The present invention relates to an improved connector for joining two tubular members together. The connector is formed by a plurality of longitudinally extending fingers extending from an end of one of tubular members and at least one locking groove in the other of the tubular members for receiving the fingers. The connector further includes a circumferentially extending wire member which is received in a notch in a head portion of each of the plurality of fingers. The wire member is preferably formed from a shape memory alloy and has an original circumference less than the circumference of a circle formed by the notches in a head portions of the fingers. The connector includes apertures through which electric wires may be connected to the shape memory alloy ring member so as to cause the shape memory alloy ring member to return to its original shape and allow release of the joint connection. PRECISION MANIPULATION WITH A DEXTROUS ROBOT HAND Ph.D. Thesis
Paul Michelman 1994 195 p
Avail: Univ. Microfilms Order No. DA9421381

In this thesis, we discuss a framework for describing and synthesizing precision manipulation tasks with a robot hand. Precision manipulations are those in which the motions of grasped objects are caused by finger motions alone (as distinct from arm or wrist motion). Experiments demonstrating the capabilities of the Utah-MIT hand are presented. This work begins by examining current research on biological motor control to raise a number of questions. For example, is the control centralized and organized by a central processor? Or is the control distributed throughout the nervous system? Motor control research on manipulation has focused on developing classifications of hand motions, concentrating solely on finger motions, while neglecting grasp stability and interaction forces that occur in manipulation. In addition, these taxonomies have not been explicitly functional. This thesis defines and analyzes a basic set of manipulation strategies that includes both position and force trajectories. The fundamental purposes of the manipulations are: (1) rectilinear and rotational motion of grasped objects of different geometries; and (2) the application of forces and moments against the environment by the grasped objects. First, task partitioning is described to allocate the fingers their roles in the task. Second, for each strategy, the mechanics and workspace of the tasks are analyzed geometrically to determine the gross finger trajectories required to achieve the tasks. Techniques illustrating the combination of simple manipulations into complex, multiple degree-of-freedom tasks are presented. There is a discussion of several tasks that use multiple elementary strategies. The tasks described are removing the top of a childproof medicine bottle, putting the top back on, rotating and regrasping a block and a cylinder within the grasp. Finally, experimental results are presented. The experimental setup at Columbia University's Center for Research in Intelligent Systems and experiments with a Utah-MIT hand is discussed. First, the overall system design is described. Two hybrid position/force controllers were designed and built. After a discussion of the entire system, experimental results are presented describing each of the basic manipulation and complex manipulation strategies. Dissert. Abstr.

ROBUST POSITION AND FORCE TRACKING CONTROL FOR A ROBOT IN CONTRACT Ph.D. Thesis
Sang-moo Lee 1993 166 p
Avail: Univ. Microfilms Order No. DA9421158

This thesis presents a robust position and force tracking control approach for a robot in contact. When a robot involves in a task of changing between free and contact motion, tracking contact position or force is a difficult problem in control. The approach uses the computed torque linearization to cancel the nonlinear dynamics of the robot. A target dynamics is then applied to the linearized system. The target dynamics relates position errors and force errors through force error compensators. Using the high-order compensators, the target dynamics guarantees smooth transition

between free and contact maneuvers, position or force tracking, and robust performance to environmental uncertainty. In case of single degree-of-freedom robots, tracking in steady states can be achieved by designing compensators, placing zeros or poles at the origin for position or force tracking control, respectively. To improve tracking performance in transient states, the H(sub infinity) control synthesis is adopted to design a compensator that minimizes H(sub infinity) optimality. The optimality is augmented to trade off between mixed sensitivities and joint loads. The designed compensator for the multi-input and multioutput system shows that the tracking performance meets the design specifications. When the environmental uncertainty is structured as a simple inertia-damper-stiffness system with unbounded coefficients, robustly stable compensators exist for all variations of the coefficients. When the uncertainty is unstructured and bounded, the H(sub infinity) robust performance condition is employed to design a compensator robust to the uncertainty. A reduced-order compensator is obtained by iteratively applying optimization to a fixed-order compensator with unknown coefficients. The computed torque linearization is subject to modeling errors in sensing, measurements, and estimations, which degrade the stability of the controlled system. A sufficient condition for stability robust to the modeling errors is derived by combining the operator theory and the small gain theorem. The condition determines the allowable limits of the modeling errors. Author

FAILURE ANALYSIS OF A REPAIRABLE SYSTEM: THE CASE STUDY OF A CAM-DRIVEN RECIPROCATING PUMP M.S. Thesis
Donald D. Dudenhoeffer Sep. 1994 100 p
(AD-A293144) Avail: CASI HC A05/MF A02

This thesis supplies a statistical and economic tool for analysis of the failure characteristics of one typical piece of equipment under evaluation: a cam-driven reciprocating pump used in the submarine's distillation system. Comprehensive statistical techniques and parametric modeling are employed to identify and quantify pump failure characteristics. Specific areas of attention include: the derivation of an optimal maximum replacement interval based on costs, an evaluation of the mission reliability for the pump as a function of pump age, and a calculation of the expected times between failures. The purpose of this analysis is to evaluate current maintenance practices of time-based replacement and examine the consequences of different replacement intervals in terms of costs and mission reliability. Tradeoffs exist between cost savings and system reliability that must be fully understood prior to making any policy decisions. DTIC

CONTROL OF MECHANICAL SYSTEMS WITH ROLLING CONTACTS: APPLICATIONS TO ROBOTICS Ph.D. Thesis
Nilanjan Sarkar 1993 165 p
Avail: Univ. Microfilms Order No. DA9413904

The problems of modeling and control of mechanical dynamic systems subject to rolling contacts are investigated. There are two important theoretical contributions in this dissertation. First, contact kinematic relationships up to second order are developed for two rigid bodies in point contact. These equations relate gross rigid body motion to the changes in the positions of the points of contact. Second, a unified approach to the control of mechanical systems subject to both holonomic and nonholonomic constraints is proposed. The basic approach is to extend the state-space to include, in the addition to the generalized coordinates and velocities, contact coordinates which describe the displacements of the contact points and their derivatives. This redundant state-space formulation provides a convenient way to specify output equations to control contact motion. The control problem is formulated as an affine nonlinear problem and a differential-geometric, control-theoretic approach is used to decouple and linearize such systems. It is shown that such a system, even though not input-state linearizable, is input-output linearizable. Further, the zero dynamics of such a system is shown to be Lagrange stable. The proposed methodology is applied to three different robotic systems: (1) wheeled mobile robots; (2) two arms manipulating an object with rolling contact between each arm and the object; and (3) a single robot arm maintaining controlled contact against a moving environment. In each case, a nonlinear controller is designed to achieve the desired performances. For mobile robots, a new control algorithm called dynamic path following is proposed and shown to be quite effective and robust. In the context of two arm manipulation, grasp adaptation through the control of contact motion is demonstrated. Maintaining rolling contact with a moving surface is formulated as an acatastatic system. The proposed scheme involves simultaneously controlling interaction forces as well as the relative (rolling) motion. In all cases, computer simulations results are presented to demonstrate the efficacy of the control schemes. Dissert. Abstr.

LINEAR MOTOR FREE PISTON COMPRESSOR Final Report
David P. Bloomfield 17 Feb. 1995 30 p
(Contract DAAL03-92-C-0016)
(AD-A293452; ARO-30443.1-CH-5) Avail: CASI HC A03/MF A01

A Linear Motor Free Piston Compressor (LMFPC), a free piston pressure recovery system for fuel cell powerplants was developed. The LMFPC consists of a reciprocating compressor and a reciprocating expander which are separated by a piston. In the past energy efficient turbochargers have been used for pressure large (over 50 kW) fuel cell powerplants by recovering pressure energy from the powerplant exhaust. A free piston compressor allows pressurizing 3 - 5 kW sized fuel cell powerplants. The motivation for pressurizing PEM fuel cell powerplants is to improve fuel cell performance. Pressurization of direct methanol fuel cells will be required if PEM membranes are to be used Direct methanol oxidation anode catalysts require high temperatures to operate at reasonable power densities. The elevated temperatures above 80 C will cause high water loss from conventional PEM membranes unless pressurization is employed. Because pressurization is an energy intensive process, recovery of the pressure energy is required to permit high efficiency in fuel cell powerplants. A complete LMFPC which can pressurize a 3 kW fuel cell stack was built. This unit is one of several that were constructed during the course of the program. DTIC

BRUSH SEAL SHAFT WEAR RESISTANT COATINGS Final Report, May 1994 - Mar. 1995
Harold Howe 28 Mar. 1995 38 p
(Contract NAS3-27383)
(NASA-CR-198950; NAS 1.26:198950; AD-A292886) Avail: CASI HC A03/MF A01

Brush seals suffer from high wear, which reduces their effectiveness. This work sought to reduce brush seal wear by identifying and testing several industry standard coatings. One of the coatings was developed for this work. It was a co-sprayed PSZ with boron-nitride added for a high temperature dry lubricant. Other coatings tested were a PSZ, chrome carbide and a bare rotor. Testing of these coatings included thermal shocking, tensile testing and wear/coefficient of friction testing. Wear testing consisted of applying a coating to a rotor and then running a sample tuft of SiC ceramic fiber against the coating. Surface speeds at point of contact were slightly over 1000 ft/sec. Rotor wear was noted, as well as coefficient of friction data. Results from the testing indicates that the oxide ceramic coatings cannot withstand the given set of conditions. Carbide coatings will not work because of the need for a metallic binder, which oxidizes in the high heat produced by friction. All work indicated a need for a coating that has a lubricant contained within itself and the coating must be resistant to an oxidizing environment. DTIC

ANALYTIC AND EXPERIMENTAL INVESTIGATION OF ROTORDYNAMIC RESPONSE AND BACKWARD WHIRL INDUCED BY SPLIT RESONANCE M.S. Thesis
Curtis E. Vejvoda Dec. 1994 135 p
(AD-A293639) Avail: CASI HC A07/MF A02

Rotordynamic response phenomena, including backward whirl, were investigated both analytically and experimentally. A two degrees-of-freedom rotor model was developed to simulate the steady state, lateral vibration characteristics of a simply supported, single disk rotor. This model includes the effects of direct and cross-coupled, linear damping and stiffness coefficients. The computer model was used to quantify the influence of bearing characteristics on rotordynamic response. The presence of split resonance, which appears to be due to separate and distinct natural frequencies in the two orthogonal lateral directions and the occurrence of backward whirl between these two frequencies was studied. The effects of geometric imperfections in the bearing sleeve, gravitational forces and bearing support stiffnesses were isolated using the experimental apparatus. It was determined that the split resonance induced backward whirl and the

different natural frequencies were caused by asymmetric stiffness of the bearing support structure as well as gravitational forces. Bearing imperfections did not create the backward whirl phenomena. The bearing support characteristics necessary to create the observed rotor orbits were determined. DTIC

FINITE ELEMENT ANALYSIS OF SMART STRUCTURES AND MODAL TESTING OF A FLEXIBLE SPACECRAFT ARM M.S. Thesis
James C. Trump Dec. 1994 58 p
(AD-A293761) Avail: CASI HC A04/MF A01

This thesis deals with analytical predictions and experimental determination of the modal frequencies and shapes associated with the arm portion of the Naval Postgraduate School's Flexible Spacecraft Simulator (FSS). A description of how piezoceramic sensors and actuators are incorporated in finite element modeling is presented. A MATLAB (tm) code conducting the finite element modeling of the arm is used to verify the modal frequencies generated via Structural Dynamic Research Corporation's I-DEAS (tm) software. Modal testing is conducted with the I-DEAS test package to determine the first four physical modal frequencies and shapes so that we may compare them with the analytical results. The results of the testing indicated that finite element analysis predicted modes one and three within an average of 23.1%, and modes two and four within an average of 4.4%. DTIC

ON THE KINEMATIC PERFORMANCE OF MECHANICAL MANIPULATORS OPERATING IN THE PRESENCE OF AN OBSTRUCTION Ph.D. Thesis
Victor Charles Rogers 1993
Avail: Issuing Activity (Univ. of Southern California, Doheny Library, Micrographics Dept., Los Angeles, CA 90089-0182)

Mechanical manipulators constitute an essential element of such technological systems as teleoperators, prosthesis, telecherics, locomotion devices, and robots. The earliest systems tended to be kinematically nonredundant and incorporated planar regional substructures. As technology advanced, systems incorporating redundant joint axes were developed. Their advantages have been categorized in terms of such criteria as slenderness, dexterity, and range of motion. Particular emphasis is placed on redundancy for avoiding workspace singularities and when the manipulator must operate in obstructed environments. The advantages provided by kinematic redundancy are offset by practical considerations including increased complexity in both basic design and control strategy. Questions remain unanswered regarding the number, type, and order of joints which a redundant system should have. No consensus exists regarding the most advantageous proportioning of link lengths. This dissertation provides a quantitative assessment of the obstruction effects in an effort to answer some of these questions. Value is placed on the size of the reachable workspace, and it is used as a figure of merit to assess kinematic performance. Kinematic performance is evaluated for a specific class of manipulator operating in the presence of a single circular or spherical obstruction. Planar and spatial designs, constructed from rigid links and incorporating planar 2R and 3R regional structures, are studied in detail. The limiting case of an infinitely redundant manipulator is established. The effects of kinematic redundancy, joint motion limitations, and the use of prismatic pairs are considered. Traditional kinematic concepts of equivalent mechanisms, mobility, and displacement analysis are used to map the boundary of the obstructed workspace for the regional structure of the manipulator. Within the workspace, parametric variations of obstacle size and location are made. Numerical integration is used to quantify the size of the region which is lost due to the obstruction. Using workspace size as a performance measure, topics of optimal link length selection and obstacle placement within the workspace are addressed. Upper bounds are established for performance improvement through joint addition or link length adjustment. Design guidelines, applicable to manipulator synthesis and workcell arrangement, are presented. Dissert. Abstr.

FLUID-FILM LUBRICATION WITH AN APPLICATION TO PISTON RINGS Ph.D. Thesis
Mohsen Esfahanian 1994 250 p
Avail: Univ. Microfilms Order No. DA9420949

This dissertation consists of four related studies. The first part provides dimensionless film thickness equations for four fluid-film lubrication regimes found for nonconformal surfaces while considering side-leakage effects. These regimes are isoviscous rigid, piezoviscous rigid, isoviscous elastic, and piezoviscous elastic. The influence or lack of influence of elastic effects from the solid surfaces and pressure-viscosity effects from the lubricant is a factor that distinguishes these regimes. Results are presented as a map of the lubrication regimes for four values of the ellipticity parameter. The second part deals with integrating artificial intelligence and conventional numerical design techniques to aid in tribological design. The study concentrates on the application of contact stresses. The result is a computer code, the Design Expert for Contact Stress, which incorporates and combines an expert system with numerical analysis techniques to aid the user in designing machine elements. This menu-driven program also performs a design compatibility analysis, which evaluates the compatibility between the specifications and the design, provides a rating on the overall design, lists reasons for the evaluation, and gives suggestions for improvements. The third part investigates the rheological effects in elastohydrodynamic lubrication. In this study the effects on fluid viscosity of pressure, temperature, shear strain rate, shear stress, and time are examined. A number of non-Newtonian models are introduced. The effects of pressure on fluid density are described. The role of solidification pressure on the density of the lubricants is also examined. The possible influence of a lubricant's viscoelastic behavior on its viscosity is considered. Finally, the influence of rheological effects on elastohydrodynamic lubrication is explained. The last part describes fundamental research into the basic mechanisms involved in piston ring lubrication. A recently developed system numerical approach is used for obtaining the lubrication characteristics of the piston ring-cylinder liner conjunction. A complete hydrodynamic and elastohydrodynamic lubrication analysis considering lubricant film shapes and pressure profiles is performed. This requires the simulation of both squeeze and entraining motion of the piston ring throughout an engine cycle. Existence of fluid-film lubrication throughout the engine cycle is examined. Dissert. Abstr.

QUALITY IN APPLIED SCIENCE
T. Sten 31 Dec. 1993 11 p
(PB95-196390; STF75-S93040) Avail: Issuing Activity (National Technical Information Service (NTIS))

Science is in many senses a special kind of craft and only skilled craftsmen are able to distinguish good work from bad. Due to the variation in approaches, methods and even philosophical basis, it is nearly impossible to derive a general set of quality criteria for scientific work outside specific research traditions. Applied science introduces a new set of quality criteria having to do with the application of results in practical situations and policy making. A scientist doing basic research relates mainly to the scientific community of which he is a member, while in applied contract research the scientist has to consider the impact of his results both for the immediate users and upon interest groups possibly being affected. Application thus raises a whole new set of requirements having to do with business ethics, policy consequences and societal ethics in general. NTIS

ORBITER RAREFIED-FLOW REENTRY MEASUREMENTS FROM THE OARE ON STS-62
R. C. Blanchard and J. Y. Nicholson (Vigyan Research Associates, Inc., Hampton, VA.) Jun. 1995 36 p
(RTOP 242-80-01-01)
(NASA-TM-110182; NAS 1.15:110182) Avail: CASI HC A03/MF A01

Acceleration data taken from the Orbital Acceleration Research Experiment (OARE) during reentry on STS-62 has been analyzed using calibration factors taken on-orbit. The data includes the flight regime from orbital altitudes down to about 100 km which covers the free-molecule-flow regime and some of the flow-transition into the hypersonic continuum. Ancillary data on orbiter position, orientation, velocity, and rotation rates have been used in models to transform the measured accelerations to the orbiter center-of-gravity, from which aerodynamic accelerations along the orbiter body axes have been calculated. Additional steps are discussed which remove residual offsets introduced in the measurements by unmodeled orbiter forces. The resulting aerodynamic accelerations and their ratios, A(sub z)/A(sub x), are discussed and compared with free-molecule-flow predictions of the aerodynamic coefficient ratios C(sub N)/C(sub A).

QUALITY ASSURANCE TENDERING AND AWARDING CONTRACTS [KWALITEITSBORGING, AANBESTEDING EN GUNNING]
Dec. 1994 54 p In DUTCH
(PB95-197760; ISBN-90-6628-186-3) Avail: Issuing Activity (National Technical Information Service (NTIS))

Standards relating to quality control can be significantly useful when tendering for and awarding contracts. However, because it is sometimes difficult to express these standards in palpable economic terms, they can (practically) never be applied as criteria for awarding contracts in accordance with U.A.R. (Uniform General Standards) 1986. Therefore it would be advisable in the future to regard the availability of a (certified) system of

quality control as being a standard requirement. To this end, a paragraph setting requirements for a quality control plan should be included in the specification. A quality control plan will be required on awarding a contract. This envisaged scenario can best achieved through a transitional phase. During this period there will be opportunity enough for removing any shortcomings in the wording and for considering standards to be required and assessment procedures. NTIS

RECOMMENDED TECHNIQUES FOR EFFECTIVE MAINTAINABILITY. A CONTINUOUS IMPROVEMENT INITIATIVE OF THE NASA RELIABILITY AND MAINTAINABILITY STEERING COMMITTEE
Dec. 1994 105 p
(NASA-TM-4628; NAS 1.15:4628) Avail: CASI HC A06/MF A02

This manual presents a series of recommended techniques that can increase overall operational effectiveness of both flight and ground based NASA systems. It provides a set of tools that minimizes risk associated with: (1) restoring failed functions (both ground and flight based); (2) conducting complex and highly visible maintenance operations; and (3) sustaining a technical capability to support the NASA mission using aging equipment or facilities. It considers (1) program management - key elements of an effective maintainability effort; (2) design and development - techniques that have benefited previous programs; (3) analysis and test - quantitative and qualitative analysis processes and testing techniques; and (4) operations and operational design techniques that address NASA field experience. This document is a valuable resource for continuous improvement ideas in executing the systems development process in accordance with the NASA 'better, faster, smaller, and cheaper' goal without compromising safety.

Stress evaluation in solids plays an important role in engineering. Many experimental techniques have therefore been developed, ranging from the destructive holedrilling method to a large number of non-destructive methods based on x-ray or neutron diffraction, photoelasticity, the determination of magnetic properties and ultrasonic measurements. The subject of this thesis is stress evaluation in metal using ultrasonic waves. The measurements are based on a phenomenon known as acoustoelasticity, i.e. the dependence of wave propagation on the state of deformation or stress in the material.

(PB95-208260; ISBN-90-407-1084-8) Copyright Avail: CASI HC A11/MF A03

The results of an experimental and numerical investigation on the fatigue behavior of uniplanar and multiplanar joints made of square hollow sections are presented in this work. This work has been carried out within the framework of the research program DCT80-1457 sponsored by the Netherlands Technical Foundation (STW). After calibration of the numerical models of the joints with the experimental results, a numerical investigation for the joint parameters for the determination of stress concentration factors (SCF's) and strain concentration factors (SNCF's) was conducted. The software 'HOTSHS' is developed which uses the data base of this parameter study to calculate the hot spot stresses at the weld toes in the various joint types investigated for a given load combination, within the range of the parameters studied. The aim of this research program is to provide stress concentration factors for the fatigue design of uniplanar and multiplanar joints in square hollow sections.

EXPERIMENTAL DETERMINATION OF PROBABILITY DISTRIBUTIONS FOR PARAMETERS OF A SALEM LIMESTONE CAP PLASTICITY MODEL Technical Report, 31 Jan. 1992 - 30 Jun. 1994
Arlo F. Fossum, Tom W. Pfeifle, and Kirby D. Mellegard 1 Jan. 1995 63 p
(Contract DNA001-92-C-0030)
(AD-A290878; RSI-0502; DNA-TR-94-39) Avail: CASI HC A04/MF A01

Marginal probability density functions and a correlation matrix are determined for parameters of the Weidlinger cap plasticity model for Salem limestone specimens originating from Bedford, Indiana. The report describes a program comprising precision laboratory testing, parameter estimation, and probability distribution model fitting. A novel testing scheme allows a complete set of material parameters to be determined from a single test specimen. Statistical properties and distributions are determined by replication. The fitted model is validated by predicting loading histories not included in the fitting database. The testing program includes uniaxial strain tests in axial strain control, unconfined compression tests in all strain control (-1 x 10(exp 6/8)), hydrostatic compression tests in load control (-0.02 MPa/s), and triaxial compression tests in axial strain control (-1 x 10(exp 5/8)), during loading and load control during unloading (-0.02 MPa/s). All specimens are tested at a constant temperature of 20 C and at a water saturation level of 50%. The validation study clearly demonstrates that the parameter estimation procedure produces high quality parameter values, and that the fitted model can not only reproduce measured data included in the fitting database, but also predicts responses from tests conducted under loading histories different from those found in the fitting database.

STATIC BEHAVIOUR OF AXIALLY LOADED UNIPLANAR AND MULTIPLANAR TUBULAR X-JOINTS
G. J. vanderVegte 1994 99 p Prepared in cooperation with Instituut TNO voor Bouwmaterialen en Bouwconstructies Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-207866) Avail: CASI HC A05

In nature, many applications of hollow sections as a structural element can be observed. Besides excellent properties with regard to resisting compression, tension, bending and torsion forces, hollow sections offer the possibility for architecturally attractive designs. In particular, circular hollow sections have proved to be suitable structural elements. Due to their shape, circular hollow sections have relatively low drag coefficients and are therefore the most favorite choice for elements subjected to wind and wave loading. In addition, the surface area of structures made of circular hollow sections, is much smaller than for comparable structures made of open structures. This, in combination with the smooth circular shape, requires lower costs for protection against corrosion and maintenance of circular members. Therefore, circular hollow sections are applied in a wide range of onshore and offshore structures, e.g. buildings, barriers, towers, bridges, offshore

platforms, etc. Since all of these structures are three dimensional, it is obvious that in many cases multiplanar connections are present at the intersection of several circular members. NTIS

N95-30586# Technische Univ., Delft (Netherlands).
FATIGUE BEHAVIOUR OF MULTIPLANAR TUBULAR JOINTS
A. Romeijn 1994 84 p Sponsored by Stichting voor de Technische Wetenschappen
(PB95-207874) Avail: CASI HC A05/MF A01

Circular hollow sections are frequently used in structures subjected to fatigue loading such as bridges, offshore structures and cranes. These sections are generally connected by direct welding of the sections to each other. For the design of these welded connections, information is required on the fatigue behavior. Especially for multiplanar connections, insufficient data is available regarding stress concentration factors (SCF's) which affect the fatigue life. Also, there is no standard for determining the fatigue strength of welded tubular joints. This has led to a divergence in the methods being used both experimentally as well as numerically. This publication presents the results of experimental and numerical research on the fatigue strength of welded tubular joints. The research projects aim to provide guidelines and design recommendations on the fatigue strength of welded tubular joints, to be proposed for inclusion in international codes of practice such as Eurocode 3. STRUCTURAL DESIGN USING EQUILIBRIUM PROGRAMMING FORMULATIONS
Stephen J. Scotti Jun. 1995 116 p
(RTOP 537-06-21-09)
(NASA-TM-110175; NAS 1.15:110175) Avail: CASI HC A06/MF A02

Solutions to increasingly larger structural optimization problems are desired. However, computational resources are strained to meet this need. New methods will be required to solve increasingly larger problems. The present approaches to solving large-scale problems involve approximations for the constraints of structural optimization problems and/or decomposition of the problem into multiple subproblems that can be solved in parallel. An area of game theory, equilibrium programming (also known as noncooperative game theory), can be used to unify these existing approaches from a theoretical point of view (considering the existence and optimality of solutions), and be used as a framework for the development of new methods for solving large-scale optimization problems. Equilibrium programming theory is described, and existing design techniques such as fully stressed design and constraint approximations are shown to fit within its framework. Two new structural design formulations are also derived. The first new formulation is another approximation technique which is a general updating scheme for the sensitivity derivatives of design constraints. The second new formulation uses a substructure-based decomposition of the structure for analysis and sensitivity calculations. Significant computational benefits of the new formulations compared with a conventional method are demonstrated. Author

MINIMIZING STRUCTURAL VIBRATIONS WITH INPUT SHAPING (TM) Final Report
Bill Singhose and Neil Singer Jan. 1995 170 p Sponsored by NASA, Washington
(Contract NAS5-32034)
(NASA-CR-189439; NAS 1.26:189439) Avail: CASI HC A08/MF A02

A new method for commanding machines to move with increased dynamic performance was developed. This method is an enhanced version of input shaping, a patented vibration suppression algorithm. This technique intercepts a command input to a system command that moves the mechanical system with increased performance and reduced residual vibration. This document describes many advanced methods for generating highly optimized shaping sequences which are tuned to particular systems. The shaping sequence is important because it determines the trade off between move/settle time of the system and the insensitivity of the input shaping algorithm to variations or uncertainties in the machine which can be controlled. For example, a system with a 5 Hz resonance that takes 1 second to settle can be improved to settle instantaneously using a 0.2 shaping sequence (thus improving settle time by a factor of 5). This system could vary by plus or minus 15% in its natural frequency and still have no apparent vibration. However, the same system shaped with a 0.3 second shaping sequence could tolerate plus or minus 40% or more variation in natural frequency. This document describes how to generate sequences that maximize performance, sequences that maximize insensitivity, and sequences that trade off between the two. Several software tools are documented and included. Author

FOURIER SERIES METHODS FOR CRACKS IN POLYGONAL PLATES AND SHELLS OF REVOLUTION Ph.D. Thesis
Frankie Man Wai Kwok 1994 145 p
Avail: Univ. Microfilms Order No. DA9422098

The objective of the study is to develop efficient numerical methods of solving fracture mechanics problems. In addition to computational efficiency, these methods must require minimal user set-up times. A final criterion is the avoidance of special crack-tip elements to capture the singular behavior. The first part of the study focuses on cracked polygonal plates under anti-plane loading. The basis of this work is the Fourier series method, which transforms a problem with a complicated geometry into a summation of half-plane problems. Through this method, the problem takes the form of a matrix equation, solution of which gives the out-of-plane displacement at any point in the plate. With this solution, the J-integral is found to be an accurate and efficient method of obtaining the stress intensity factor. A number of examples are given to illustrate the versatility of this Fourier series method. The second part of the study continues onward to shells of revolution with circumferential through cracks. The shell problem is formulated as a state vector equation. With an asymptotic-numeric procedure, the edge stiffness matrix for each Fourier circumferential harmonic is obtained. The next step involves constructing the expansion and contraction matrices, which relate the Fourier harmonics of the crack domain to those of the whole circumferential domain. By combining the edge stiffness matrices with the expansion and contraction matrices, a matrix equation is formed. Solution of this equation yields the crack-face displacements satisfying the traction free condition in the crack domain. Numerous examples are presented, which include cracks at the middle sections or fixed ends of cylindrical shells under tensile, bending, or torsional loads. With the above methods, various fracture mechanics parameters can be obtained. These include the crack driving force, the stress intensity factor, the crack opening displacement and area. For the

anti-plane problem, stress intensity factor results compare well with an analytical solution. For shells of revolution, comparisons are made with analytical results from the shallow shell and thin shell theories, and the finite element method. These comparisons highlight the limitations of the different approaches. Dissert. Abstr.

A SIMPLE AND ACCURATE TECHNIQUE FOR MONITORING CRACK GROWTH BEHAVIOR USING A WAVE FORM ANALYZER Final Report

D. E. Leighton and Ronald T. Abbott Jan. 1995 16 p

(AD-A293161; ARCCB-TR-95001) Avail: CASI HC A03/MF A01

A technique for monitoring the change in compliance of a standard three-point bend specimen during fatigue cycling has been developed. This method allows for accurate measurement of the load-line displacement it changes that occur as a crack grows from the notch. The significance of this technique is that it allows accurate determination of crack grows behavior throughout the life cycle of the specimen when a clip gage is impractical or impossible to use. RESIDUAL STRESSES AND STRESS CORROSION CRACKING IN PIPE FITTINGS

Ronald J. Parrington, James J. Scott, and Freddie Torres Jun. 1994 8 p Presented at the Fontevraud 3 Conference, Chinon, France, 12-16 Sep. 1994

(Contract DE-AC12-76SN-00052)

(DE95-009332; KAPL-4798; CONF-9409321-1) Avail: CASI HC A02/MF A01

Residual stresses can play a key role in the SCC performance of susceptible materials in PWR primary water applications. Residual stresses are stresses stored within the metal that develop during deformation and persist in the absence of external forces or temperature gradients. Sources of residual stresses in pipe fittings include fabrication processes, installation and welding. There are a number of methods to characterize the magnitude and orientation of residual stresses. These include numerical analysis, chemical cracking tests, and measurement (e.g., X-ray diffraction, neutron diffraction, strain gage/hole drilling, strain gage/trepanning, strain gage/section and layer removal, and acoustics). This paper presents 400 C steam SCC test results demonstrating that residual stresses in as-fabricated Alloy 600 pipe fittings are sufficient to induce SCC. Residual stresses present in as-fabricated pipe fittings are characterized by chemical cracking tests (stainless steel fittings tested in boiling magnesium chloride solution) and by the sectioning and layer removal (SLR) technique. THERMAL-MECHANICAL FATIGUE CRACK GROWTH IN AIRCRAFT ENGINE MATERIALS Ph.D. Thesis

Yi Dai 1993 353 p

(ISBN-0-315-86543-1) Avail: Univ. Microfilms Order No. DANN86543

This thesis summarizes the major technical achievements obtained as a part of a collaborative research and development project between Ecole Polytechnique and Pratt & Whitney Canada. These achievements include: (1) a thermal-mechanical fatigue (TMF) testing rig which is capable of studying the fatigue behaviors of gas turbine materials under simultaneous changes of temperatures and strains or stress; (2) an advanced alternative current potential drop (ACPD) measurement system which is capable of performing on-line monitoring of fatigue crack initiation and growth in specimen testing under isothermal and TMF conditions; (3) fatigue crack initiation and short crack growth data for the titanium specimens designed with notch features associated with bolt holes of compressor discs; (4) thermal-mechanical fatigue crack growth data for two titanium alloys being used in PWC engine components, which explained the material fatigue behavior encountered in full-scale component testing; (5) a complete fractographic analysis for the tested specimens which enhanced the understanding of the fatigue crack growth mechanisms and helped to establish an analytical crack growth model; and (6) application of the ACPD fatigue crack monitoring technique to single tooth firtree specimen (STFT) LCF testing of PWA 1480 single crystal alloy. Finally, a comprehensive discussion concerning the results pertaining to this research project is presented. Dissert. Abstr.

EFFECT OF CYCLIC LOADING ON THE CREEP PERFORMANCE OF SILICON NITRIDE

A. A. Wereszczak, M. K. Ferber, T. P. Kirkland, and C. K. J. Lin (National Central Univ., Chung-Li, Taiwan.) 1995 8 p Presented at the ASME International Gas Turbine and Aeroengine Congress and Exposition: Land, Sea and Air, Houston, TX, 5-8 Jun. 1995

(Contract DE-AC05-84OR-21400)

(DE95-010289; CONF-950629-6) Avail: CASI HC A02/MF A01

Tension-tension cyclic fatigue tests (triangular waveform, sigma(sub max) = 100 MPa, R = 0.1) were conducted on hot isostatically pressed (HIPed) silicon nitride at frequencies spanning several orders of magnitude (5.6 x 10(exp-6) to 0.1 Hz or 10(exp -3) MPa/s to 18 MPa/s) at 1,370 C in air. The amount of cyclic creep strain was found to be a function of the frequency or stressing rate with greater strains to failure observed as the frequency or stressing rate decreased. The total strain was viewed as the sum of elastic, anelastic (or transient recoverable), and plastic (viscous or non-recoverable) strain contributions, after the empirical Pao and Marin model. The plastic strain was found to be the dominant component of the total creep and was unsatisfactorily represented by the Pao and Marin model. To circumvent this, a time exponent was introduced in the plastic strain term in the Pao and Marin model. This modification resulted in good correlation between model and experiment at the slower frequencies examined but over-predicted the cyclic creep strain at the faster frequencies. The utility of using the modified Pao and Marin model to predict cyclic creep response from static creep and strain relaxation tests is described. DOE

DAMAGE DOSIMETRY AND EMBRITTLEMENT MONITORING OF NUCLEAR PRESSURE VESSELS IN REAL TIME BY MAGNETIC PROPERTIES MEASUREMENT Final Report

A. M. Ougouag, J. F. Stubbins, J. F. Williams, and Wei-Ja Shong Apr. 1995 35 p

(Contract DE-FG02-90ER-13030)

(DE95-011454; DOE/ER-13030/T1) Avail: CASI HC A03/MF A01

This program developed a nondestructive technique for gauging the progress of embrittlement of nuclear pressure vessel steels (PVS) by means of monitoring radiation-induced changes in magnetic properties. The technique was developed by running a series of experiments in reactor on typical nuclear pressure vessel steels and weldment material. Following irradiation, changes in magnetic properties were measured and correlated with irradiation dose and with mechanical properties changes, where possible. The changes in magnetic properties were unique to the irradiation environment, and were much larger than those produce by thermal aging in the absence of irradiation. Special techniques for magnetic properties change measurement were developed and complimented by more standard magnetic properties measurement techniques including SQUID measurements. The results of the experiments revealed that magnetic properties were very sensitive to irradiation. Changes in microstructurally-related magnetic properties of as much as 40% were noted after irradiation exposure of as little as 10(exp 17) n/sq cm (E greater than 0.1 MeV). The magnetic properties changes plateaued out after doses of around as 10(exp 18) n/cm(sup 2) (E greater than 0.1 MeV). It is unclear whether further changes would be noted at higher doses which would also be useful for tracking the embrittlement phenomenon. This is recommended for further study. The work supported here resulted in several publications in the open scientific literature. DOE

THE 10TH INTERNATIONAL CONFERENCE ON THE STRENGTH OF MATERIALS

P. McQuay 26 Aug. 1994 4 p Conference held in Sendai, Japan, 21-26 Aug. 1994

(AD-A292335; AOARD-TR-94-24) Avail: CASI HC A01/MF A01

The ICSMA 10 conference provided an excellent snapshot of our current understanding of the fundamental mechanisms of the deformation and failure of crystalline materials. One of the more provocative papers was presented by Prof Vitek who presented a model linking brittle intergranular fracture caused by the structure of segregated grain boundaries in alloys, and the grain boundary structures in intermetallics. Several interesting papers

of an empirical nature were also presented, including reviews of nano-laminated materials, high strength, ductility and stiffness quasicrystalline Al-based alloys, and a comprehensive review of superplastically formable fine-grained ceramics. DTIC

ENERGY FLOW ANALYSIS OF COUPLED STRUCTURES Ph.D. Thesis
Phillip Eung-Ho Cho 1993 336 p
Avail: Univ. Microfilms Order No. DA9420802

Energy flow analysis (EFA) is an analytical tool for prediction of the frequency-averaged vibrational response of built-up structures at high audible frequencies. The procedure is based on two developments; firstly, the derivation of the partial differential equations that govern the propagation of energy-related quantities in simple structural elements such as rods, beams, plates, and acoustic cavities; secondly, the derivation of coupling relationships in terms of energy-related quantities that describe the transfer of energy for various joints (e.g., beam-to-beam, plate-to-plate, and structure-to acoustic field couplings). In this investigation, EFA is used to predict the vibrational response of various coupled structures. In the process of predicting the vibrational response of the coupled structures, the energy flow coupling relationships at the joints of these structures are derived. In addition, the finite element formulation of the governing energy equations are developed. Because the energy density is discontinuous at the joint, a special global assembly procedure is developed to assemble the finite element matrix equations into global matrix equations. The global matrix assembly procedure is predicated on the development of joint element matrix equations using energy flow coupling relationships for various structural joints. The results predicted by EFA for a frame structure with a three-dimensional joint, where four wave types propagate in the structure, are shown to be a reasonable approximation of the frequency-averaged 'exact' energetics, which are computed from classical displacement solutions. The accuracy of the results predicted by EFA increased with high mode count and modal overlap factor or high non-dimensional wavenumber band and non-dimensional damped wavenumber band in the frequency band of interest. An experimental investigation of vibrational response of a light truck frame structure was performed to verify the results of EFA when applied to structures of complicated geometry. The predicted frequency-averaged (one-third octave band) vibrational response of the truck frame structure were in good agreement with the experimental results even with a crude simulation model. The EFA results also showed the important energy transmission mechanisms in these applications to built-up structures. Dissert. Abstr.

A FINITE ELEMENT FORMULATION FOR THE TIME DOMAIN VIBRATION ANALYSIS OF AN ELASTIC-VISCOELASTIC STRUCTURE Ph.D. Thesis
Richard Gerard Szumski 1993 216 p
Avail: Univ. Microfilms Order No. DA9415670

The equations of motion for the vibration study of a partially elastic and partially linearly viscoelastic structure are developed in the time domain. The unique feature of these equations is that they contain both differential and integral terms. The integral terms are convolution integrals whose convolution is made between the time derivative of the viscoelastic relaxation modulus and the displacement history. They account for viscoelastic damping of the structure. The equations are simplified through the solution of a real eigenvalue problem which is subsequently used to decouple all but the damping term. A numerical solution procedure is presented using the finite element method for the spatial domain and a Runge Kutta-Verner numerical integration routine for temporal domain of the problem. Partial decoupling of the equations of motion reduces computation time and saves storage space. The convolution integrals are evaluated at each time step using the trapezoidal rule. Two new viscoelastic constitutive laws are introduced that are shown to characterize material properties over a broad frequency spectrum with few material parameters. They are convenient to work with because they have simple rational forms in both the time and frequency domains and also unconditionally obey the second law of thermodynamics. To verify the theory, computer program, and new viscoelastic constitutive laws, a simple elastic-viscoelastic structure known as a constrained layer damper was constructed and tested. The displacement history of the constrained layer damper was measured as an initial static displacement was suddenly released. Good agreement was obtained between the measurements and the numerical simulation of the same event using the theory developed here with the new constitutive laws. The solution procedure is a viable method for solving for the vibratory response of viscoelastically damped structures and is suitable for large-scale finite element analysis through a modified form of Guyan reduction. The new viscoelastic constitutive laws appear to be robust in characterizing the viscoelastic materials used in the study. Dissert. Abstr.

STUDIES IN NON-LINEAR MULTI-MODE RESPONSES OF HARMONICALLY EXCITED RECTANGULAR PLATES WITH INTERNAL RESONANCES Ph.D. Thesis
Seo Il Chang 1993 186 p
Avail: Univ. Microfilms Order No. DA9420796

Nonlinear flexural vibrations of a rectangular plate with uniform stretching are studied for the case when it is harmonically excited with forces acting normal to the midplane of the plate. Through the Galerkin procedure, the von Karman equations of motion are reduced to a coupled set of nonlinear ordinary differential equations governing the motions of the N-modes. The physical phenomena of interest here arise when the plate has two distinct linear modes of vibration with nearly the same natural frequency. When the two modes are in primary or secondary resonance with the external excitation, the response of the plate can be approximated by two coupled modal equations governing the motions of the two modes in internal resonance. The method of averaging is utilized in the two resonance cases to transform the two nonlinear modal equations into sets of four dimensional dynamical systems which govern the amplitudes and phases of the two modes. The averaged systems are studied in detail by using local bifurcation theory and it is shown that, depending on the spatial distribution of the external forces, the plate can undergo harmonic motions either in one of the two individual modes or in a mixed-mode. The mixed-mode motion can be in the form of either a standing wave or a traveling wave. Stable single-mode and mixed-mode solutions can also coexist over a wide range in the amplitudes and frequency of excitation. For low damping levels, the presence of Hopf bifurcations in the mixed-mode response leads to complicated amplitude-modulated dynamics including period-doubling bifurcations, chaos, coexistence of multiple chaotic motions, and crisis, whereby the chaotic attractors suddenly disappear and the plate resumes small amplitude harmonic motions in a single-mode. The averaged equations for the case of subharmonic motions of order-three are also found to exhibit complicated dynamics including periodic and chaotic solutions. The conservative limit of the two-mode approximation of the plate equations is then studied by using the canonical averaging technique. The integrable autonomous system is found to have homoclinic and heteroclinic orbits that are destroyed by external forcing into chaotic motions. Dissert. Abstr.

(IFTR-1/1995) Avail: CASI HC A03/MF A01

Up to this point in time, either an elastic plate or a rigid-plastic plate have been used as computer models for the cover. In this study the author uses a model of an elastic-ideally plastic plate as a model which most resembles reality and makes it possible to estimate the deformation of the cover during the entire loading process, i.e. until the moment its ultimate load-bearing strength is reached. The purpose of this study was to provide a complete analytical description of the deformation of the plate as its load increases to a point of partial or complete plasticization. The author examines an elastic-plastic plate with rotational geometric and loading symmetry which covers a container filled with an ideal liquid. The plate is subjected to quasistatic loading. MODELING MULTI-BEAM STRUCTURES FOR CONTROL Ph.D. Thesis
Hanching Grant Wang 1994 108 p
Avail: Univ. Microfilms Order No. DA9420511

A new approach to find the 1-D homogeneous beam model for a

beam-like repetitive structure is proposed. The displacement field of the repetitive structure is approximated by polynomials; the periodic cross-sectional mass and stiffness matrices are obtained by energy equivalence; then the 1-D periodic beam model is formed by Hamiltonian formulation. The 1-D periodic beam model is further homogenized into an equivalent 1-D homogeneous beam model using the additive property of flexibility. A new tabulated mode calculation for chained multibeam structures is also presented. The characteristic matrices (CM's) of a simple beam with various boundary conditions are derived via functional analysis. This derivation reveals a simple rule to write down these matrices by inspection. A multibeam structure is a collection of homogenized beam models coupled through boundary conditions. The CM of the multibeam structure is derived to show that it is a binary composition of the CM's of the simple beam. The CM of a multibeam structure then can be obtained in a tabulated scheme. This greatly simplifies the formation of CM's for multibeam structures. The major contribution is the new systematic modeling approach, the observation of additivity property in homogenization, the resulted homogenized beam model operators, the formation of simple beam's CM's by inspection, and the novel demonstration that the CM of a multibeam structure is composed from the CM of a simple beam. Dissert. Abstr.

AN EVALUATION OF THE IOSIPESCU SPECIMEN FOR COMPOSITE MATERIALS SHEAR PROPERTY MEASUREMENT Ph.D. Thesis

Henjen Ho Jul. 1991 203 p Sponsored by Virginia Tech NSF Center for High Performance Polymeric Adhesives and Composites

(Grant NAG1-1053)

(NASA-CR-198755; NAS 1.26:198755) Avail: CASI HC A10/MF A03

A detailed evaluation of the suitability of the Iosipescu specimen tested in the modified Wyoming fixture is presented. An experimental investigation using conventional strain gage instrumentation and moire interferometry is performed. A finite element analysis of the Iosipescu shear test for unidirectional and cross-ply composites is used to assess the uniformity of the shear stress field in the vicinity of the notch, and demonstrate the effect of the nonuniform stress field upon the strain gage measurements used for the determination of composite shear moduli. From the test results for graphite-epoxy laminates, it is shown that the proximity of the load introduction point to the test section greatly influences the individual gage readings for certain fiber orientations but the effect upon shear modulus measurement is relatively unimportant. A numerical study of the load contact effect shows the sensitivity of some fiber configurations to the specimen/fixture contact mechanism and may account for the variations in the measured shear moduli. A comparison of the strain gage readings from one surface of a specimen with corresponding data from moire interferometry on the opposite face documented an extreme sensitivity of some fiber orientations to eccentric loading which induced twisting and yielded spurious shear stress-strain curves. In the numerical analysis, it is shown that the Iosipescu specimens for different fiber orientations have to be modeled differently in order to closely approximate the true loading conditions. Correction factors are needed to allow for the nonuniformity of the strain field and the use of the average shear stress in the shear modulus evaluation. The correction factors, which are determined for the region occupied by the strain gage rosette, are found to be dependent upon the material orthotropic ratio and the finite element models. Based upon the experimental and numerical results, recommendations for improving the reliability and accuracy of the shear modulus values are made, and the implications for shear strength measurement discussed. Further application of the Iosipescu shear test to woven fabric composites is presented. The limitations of the traditional strain gage instrumentation on the satin weave and high tow plain weave fabrics is discussed. Test results of a epoxy based aluminum particulate composite is also presented. A modification of the Iosipescu specimen is proposed and investigated experimentally and numerically. It is shown that the proposed new specimen design provides a more uniform shear stress field in the test section and greatly reduces the normal and shear stress concentrations in the vicinity of the notches. While the fabrication and the material cost of the proposed specimen is tremendously reduced, it is shown the accuracy of the shear modulus measurement is not sacrificed. Author

POST-IMPACT FATIGUE OF CROSS-PLIED, THROUGH-THE-THICKNESS REINFORCED CARBON/EPOXY COMPOSITES M.S. Thesis - Clemson Univ.

Thomas E. Serdinak May 1994 176 p

(NASA-TM-110625; NAS 1.15:110625) Avail: CASI HC A09/MF A02

An experimental investigation of the post-impact fatigue response of integrally woven carbon/epoxy composites was conducted. Five different through-the-thickness (TTT) reinforcing fibers were used in an experimental textile process that produced an integrally woven (0/90/0/90/0/90/0/90/0)(sub T) ply layup with 21K AS4 carbon tow fiber. The resin was Hercules 3501-6, and the five TTT reinforcing fibers were Kevlar, Toray carbon, AS4 carbon, glass, and IM6 carbon. The purpose of this investigation was to study the post-impact fatigue response of these material systems and to identify the optimum TTT fiber. Samples were impacted with one half inch diameter aluminum balls with an average velocity of 543 ft/sec. Post-impact static compression and constant amplitude tension-compression fatigue tests were conducted. Fatigue tests were conducted with a loading ratio of R=-5, and frequency of 4 Hz. Damage growth was monitored using x-radiographic and sectioning techniques and by examining the stress-strain response (across the impact site) throughout the fatigue tests. The static compressive stress versus far-field strain response was nearly linear for all material groups. All the samples had a transverse shear failure mode. The average compressive modulus (from far-field strain) was about 10 Msi. The average post-impact static compressive strength was about 35.5 Ksi. The IM6 carbon sample had a strength of over 40 Ksi, more than 16 percent stronger than average. There was considerable scatter in the S-N data. However, the IM6 carbon samples clearly had the best fatigue response. The response of the other materials, while worse than IM6 carbon, could not be ranked definitively. The initial damage zones caused by the impact loading and damage growth from fatigue loading were similar for all five TTT reinforcing materials. The initial damage zones were circular and consisted of delaminations, matrix cracks and ply cracks. Post-impact fatigue loading caused delamination growth, ply cracking and fiber bundle failures, typically 45 deg from impact load direction. During the initial 97 percent of fatigue life, delaminations, ply cracks and fiber bundle failures primarily grew at and near the impact site. During the final 3 percent of life, damage grew rapidly transverse to the loading direction as a through-the-thickness transverse shear failure. The stress-strain response was typically linear during the initial 50 percent of life, and stiffness dropped about 20 percent during this period. During the next 47 percent of life, stiffness dropped about 34 percent, and the stress-strain response was no longer linear. The stiffness decreased about 23 percent during the final 3 percent of life. These trends were typical of all the materials tested. Therefore, by monitoring stiffness loss, fatigue failure could be accurately anticipated. Author

LARGE DEFORMATION FAILURE MECHANISMS IN NONLINEAR SOLIDS Annual Technical Report, 1 Jan. 1992 - 31 Dec. 1994

Cornelius O. Horgan 30 Jan. 1995 17 p

(Contract F49620-92-J-0112)

(AD-A293010; AFOSR-95-0182TR) Avail: CASI HC A03/MF A01

This work was concerned with research on fundamental mechanics and mathematics of large deformation induced failures in nonlinear solids. The specific area investigated was that of void nucleation and growth due to large deformations in nonlinear solids. Research on cavitation phenomena, which serve as a precursor to fracture, is crucial to the understanding of failure mechanisms in rubber-like solids (e.g. polymers, solid rocket propellants) and of ductile fracture processes in metals. Mathematically, the work involves investigation of singular solutions of the second-order quasilinear system of partial differential equations describing equilibrium states of nonlinearly elastic bodies. For radially symmetric deformations, the basic problem reduces to a bifurcation problem for a single second-order nonlinear ordinary differential equation. Particular emphasis was placed on the effect of material inhomogeneity, compressibility and anisotropy on void nucleation and growth. DTIC

RESPONSE OF DUAL-LAYERED STRUCTURES SUBJECTED TO

SHOCK PRESSURE WAVE M.S. Thesis
Thomas P. Brasek Dec. 1994 85 p
(AD-A293731) Avail: CASI HC A05/MF A01

The response of coated, metallic structures subjected to shock pressure waves is studied. The coating is either an elastic material or nearly incompressible rubber of variable stiffness separating the structure from an air or water medium. The stress, nodal velocity, and internal energy of the coated structure are compared to a system without a coating (homogeneous system) to examine the effect of various coating types and configurations on the response of the structure to shock conditions. The results show that a mismatch of impedance, rho c sub o, between the coating and structure governs the degree of energy exchange between the coating and structure at the interface. The impedance mismatch between the structure and a rubber coating at the threshold value is termed the critical difference. If the impedance mismatch exceeds the critical difference, the dynamic response will be more adverse. A softer coating generally has a smaller impedance and tends to concentrate stress wave energy in the underlying structure. DTIC

(DE95-009577; SAND-94-2302C; CONF-950550-2) Avail: CASI HC A02/MF A01

Research at Sandia National Laboratories has shown a strain rate dependence of many materials used in the production of parachutes. Differences in strength of 30% have been found between strain rates of 12/s and slow rates normally used to define material properties for lightweight nylon cloth. These structures are sometimes deployed in a rapid fashion and the loading is experienced in milliseconds; the production of material data in the same loading regime is required for full understanding of material response. Also, material behavior suitable for structural analysis of these structures is required for successful analysis. This is especially important when different materials are used in the same fabric structure. Determining the distribution of load to various portions of a nylon and Kevlar parachute requires the correct moduli and material behavior in the analytical model. The effect of strain rate on the material properties of nylon and Kevlar components commonly used in parachute construction are reported in this paper. These properties are suitable for use in analytical models of these fabric structures. DOE

NONLINEAR DYNAMICS AND CHAOTIC MOTIONS OF A SINGULARLY PERTURBED NONLINEAR VISCOELASTIC BEAM Ph.D. Thesis
Ioannis Theodorou Georgiou 1993 338 p
Avail: Univ. Microfilms Order No. DA9420829

The dynamics of one- or two-dimensional structures such as rods, beams, plates, etc., is usually described by one- or two-dimensional nonlinear partial or integro-partial differential equations (PDE's). The equations of motion of such structural systems, with the associated boundary conditions, are amenable to numerical study and to some extent to analytical study. In practice there are many complex structural systems composed of simpler structural members or subsystems with well diverse flexibilities. A simple example is that of a frame comprised of a flexible beam mounted on two relatively stiff columns. The objective of this investigation is to relate the dynamics of a given structure to the dynamics of a simpler structure which is obtained in the limit when the much stiffer substructure of the system is assumed to be perfectly rigid. Without loss of generality, we study both analytically and numerically the dynamics of a representative complex structure, the frame. More precisely, it consists of a nonlinear viscoelastic beam hinged at its ends to two linear viscoelastic columns (supports). We view the equations of motion of the frame structure with sufficiently stiff supports as a singular perturbation of the simpler structure: the nonlinear beam pinned on rigid supports. By applying the Galerkin reduction method, we approximate the equations of motion (coupled PDEs) by a system of a finite number of coupled nonlinear oscillators interacting with a finite number of linear oscillators. Under certain conditions on system parameters, this finite system of ordinary differential equations (ODE's) constitutes the core or 'backbone' of the coupled integro-partial differential equations of motion, an infinite dimensional nonlinear dynamical system. By applying the singular perturbation methodology and the theory of invariant manifolds, we show that for sufficiently stiff linear oscillators (stiff supports) the steady state behavior including nonlinear vibrations and chaotic motions of the above finite dynamical system (full order system) is described by a system of lower dimensions. This reduced system is defined on a nonlinear invariant manifold of the full order system and it possesses symmetry properties that are exactly the same as those of the degenerate reduced system, i.e., the system obtained in the limit when the linear oscillators are assumed to be perfectly rigid. A COMPUTATIONAL PROCEDURE FOR MULTIBODY SYSTEMS INCLUDING FLEXIBLE BEAM DYNAMICS
J. D. Downer, K. C. Park, and J. C. Chiou Apr. 1990 42 p
(Grant NAG1-756)
(NASA-CR-199035; NAS 1.26:199035; CU-CSSC-90-08) Avail: CASI HC A03/MF A01

A computational procedure suitable for the solution of equations of motions for flexible multibody systems has been developed. The flexible beams are modeled using a fully nonlinear theory which accounts for both finite rotations and large deformations. The present formulation incorporates physical measures of conjugate Cauchy stress and covariant strain increments. As a consequence, the beam model can easily be interfaced with real-time strain measurements and feedback control systems. A distinct feature of the present work is the computational preservation of total energy for undamped systems; this is obtained via an objective strain increment/stress update procedure combined with an energy-conserving time integration algorithm which contains an accurate update of angular orientations. The procedure is demonstrated via several example problems. Author

APPLICATION OF SHALLOW SHELL STABILITY TO PLANT MORPHOGENESIS BY FOURIER SERIES Ph.D. Thesis
Cheng-Hsiu Wu 1994 175 p
Avail: Univ. Microfilms Order No. DA9414679

A Fourier series method of solution is presented for shallow shell buckling problems. The shallow shell equations are generally referred to as the von Karman equations, or the Marguerre equations if initial displacement exists. These equations were first solved by the Navier type solutions for a rectangular plate with simply supported boundaries. The method takes full advantage of the fast Fourier transform and a straightforward direct iteration is employed. An edge function method using Fourier series was later developed to handle shallow shells in polygonal platforms. Fundamental solutions that satisfy the homogeneous parts of the Marguerre equations are superimposed to match the prescribed boundary conditions for both the plate bending and in-plane problems, while the two-dimensional Fourier transform handles the inhomogeneity. For a convex polygon, the whole shallow shell is considered as one element, therefore, the set-up time is minimum. In the effort to explain plant morphogenesis by the principle of minimum potential energy, the method was used to solve several examples that emulate plant growth. Preliminary results show that the buckling pattern of a shallow shell experiencing upward pressure and thermal expansion is sensitive to the boundary conditions and the initial shape of the surface. Dissert. Abstr.

A NUMERICAL ANALYSIS OF CRACK GROWTH IN MICROCRACKING CERAMIC AND CERAMIC COMPOSITES
S. B. Biner 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract W-7405-eng-82)
(DE95-010132; IS-M-820; CONF-941144-140) Avail: CASI HC A02/MF A01

A set of numerical analyses of crack growth was performed to elucidate the influence of microcracking on the fracture behavior of microcracking ceramic and ceramic composites. The random nucleation, orientation and size effects of discrete nucleating microcracks and resulting interactions are fully accounted for in a hybrid finite element model. The results obtained from the finite element analysis are compared with the continuum description

of the microcracking. Although continuum description can provide a reasonable estimation of shielding, it fails to resolve the details of micromechanism of toughening resulting from microcracking, since not every shielding event during the course of crack extension corresponds to an increase in the Rcurve. Moreover, as seen in the composite cases, the local events leading to toughening behavior may not be associated with the microcracking even in the presence of large population of microcracks. DOE

AN EXTREMUM PRINCIPLE FOR THE ANALYSIS AND DESIGN OF CONSTITUTIVELY NONLINEAR SYSTEMS Ph.D. Thesis
Sheldon Kent Plaxton 1994 157 p
Avail: Univ. Microfilms Order No. DA9423292

The actual nonlinear constitutive character of most elastic materials is often approximated in engineering analysis by a linear relation-generalized Hooke's law. This approximation may introduce significant error into an analysis problem. This dissertation presents and demonstrates an approach for equilibrium analysis of a class of constitutively nonlinear systems within the context of small deformation (kinematically linear) elasticity. The approach is given in the form of an extremum principle stated in terms of mixed stress and displacement field variables. Such fields represent a pointwise additive decomposition of the total stress field throughout the material domain. Nonlinear constitutive behavior is achieved through functional bounds on the individual stress component fields, in combination with a set of constraints which assure satisfaction of equilibrium and boundary conditions. A finite-dimensional approximation of the extremum problem statement is obtained through the introduction of discrete representations of the problem fields. Numerical solutions for the resulting convex constrained minimization problem are obtained using an established minimization routine. Examples are presented which demonstrate the substantial flexibility available in specifying constitutive behavior within the model. Applications of the described modeling approach within the context of nonconservative (inelastic) systems are also discussed. In addition, extensions of the established framework to problems of optimal design are presented. Specifically, a methodology for predicting the optimal distribution of nonlinear material properties, as defined for the additive representation, is described and demonstrated. Dissert. Abstr.

A MODE DECOMPOSITION BASED FINITE ELEMENT FORMULATION FOR THE NONLINEAR DYNAMICS OF FLEXIBLE SPATIAL STRUCTURES AND MECHANISMS Ph.D. Thesis
Joseph Francis DCosta 1994 146 p
Avail: Univ. Microfilms Order No. DA9422294

A mode decomposition based finite element formulation is presented for the nonlinear dynamics of spatial structures. The formulation admits finite deformation, including finite extension, shear and torsion and incorporates all inertial effects that significantly effect the dynamics of a multibody system. In addition, the present development eliminates the shear and membrane locking phenomena that arise due to the inability of a finite element to capture pure bending without the introduction of shear and membrane modes. In this regard the finite element is very well suited to the modeling of the components of a multibody system where finite deformation is expected and could cause a component to curve significantly. Since the locking phenomena manifests itself through the introduction of spurious high frequency components to the system response, its elimination mitigates computational difficulties in the solution of the equations of a dynamical system. An inertia operator, which is consistent with the mode decomposition based formulation of the stiffness operator, is derived. This operator, besides contributing to the accuracy with which the kinematics of the beam is captured, also leads to a better approximation of the total kinetic energy content of a multibody system in a finite dimensional approximation setting. A time integration algorithm, based on a singularity free representation of finite rotations, is presented. However, unlike similar representations in the literature, the present time stepping procedure is totally free of the numerical singularities introduced due to computer round-off errors. A rigid body formulation, employing kinematic variables identical to those used in the flexible beam, is presented to enable the unified modeling of interconnected rigid and flexible components in a multibody system if desired. Several examples are presented to verify the formulations. Dissert. Abstr.

(DE95-009034; CONF-950740-16) Avail: CASI HC A02/MF A01

One of the current tasks within the U.S. Nuclear Regulatory Commission (NRC)-funded Heavy Section Steel Technology Program (HSST) at Oak Ridge National Laboratory (ORNL) is the continuing development of the FAVOR (Fracture, analysis of Vessels: Oak Ridge) computer code. FAVOR performs structural integrity analyses of embrittled nuclear reactor pressure vessels (RPVs) with stainless steel cladding, to evaluate compliance with the applicable regulatory criteria. Since the initial release of FAVOR, the HSST program has continued to enhance the capabilities of the FAVOR code. ABAQUS, a nuclear quality assurance certified (NQA-1) general multidimensional finite element code with fracture mechanics capabilities, was used to generate a database of stress-intensity-factor influence coefficients (SIFIC's) for a range of axially and circumferentially oriented semieliptical inner-surface flaw geometries applicable to RPV's with an internal radius (Ri) to wall thickness (w) ratio of 10. This database of SIRC's has been incorporated into a development version of FAVOR, providing it with the capability to perform deterministic and probabilistic fracture analyses of RPVs subjected to transients, such as pressurized thermal shock (PTS), for various flaw geometries. This paper discusses the SIFIC database, comparisons with other investigators, and some of the benchmark verification problem specifications and solutions. DOE

NUMERICAL EVALUATION OF THREE-DIMENSIONAL CRACK-TIP INTEGRALS FOR LAYERED ANISOTROPIC SOLIDS Ph.D. Thesis
Albert John DiNicola 1993 162 p
Avail: Univ. Microfilms Order No. DA9412745

A general purpose three-dimensional boundary element analysis computer code was developed to solve the boundary integral equations (BIE's) of anisotropic elasticity. The code is a significant advancement in that it can treat full material anisotropy. Fundamental integral kernels used for the numerical solution, previously defined improperly in the literature, were correctly developed. The computer program directly computes all singular integrals arising from the BIEs, including the strongly singular Cauchy Principal Value (CPV) integrals. In this way, conventional indirect techniques were avoided and significant insight into the nature of the CPV integral was gained. Benchmark stress analyses for both isotropic and anisotropic material behavior showed the program results to be highly accurate. A multizone substructuring algorithm was incorporated into the program and demonstrated comparable accuracy. The program was applied in conjunction with the crack tip J-integral in order to compute the interface crack fracture mechanics parameters for several bodies. The J-integral was decomposed into pure Mode 1, 2, and 3 components to yield physically meaningful fracture parameters. Using the decomposed components the near tip J-integral was rigorously equated to a remote contour integral plus an area integral. Results proved to be accurate for both isotropic and anisotropic materials. Using a relatively coarse mesh of nonsingular elements, the difference between closed-form fracture mechanics and boundary

element solutions were 6 percent or less. Mixed mode results for interface cracks between dissimilar anisotropic solids were generated; these results have direct application in the study of delamination cracks between plies of fiber reinforced polymer composites. Dissert. Abstr.

The numerical solution procedure for multibody dynamics (MBD) systems is termed a staggered MBD solution procedure that solves the generalized coordinates in a separate module from that for the constraint force. This requires a reformulation of the constraint conditions so that the constraint forces can also be integrated in time. A major advantage of such a partitioned solution procedure is that additional analysis capabilities such as active controller and design optimization modules can be easily interfaced without embedding them into a monolithic program. After introducing the basic equations of motion for MBD system in the second section, Section 3 briefly reviews some constraint handling techniques and introduces the staggered stabilized technique for the solution of the constraint forces as independent variables. The numerical direct time integration of the equations of motion is described in Section 4. As accurate damping treatment is important for the dynamics of space structures, we have employed the central difference method and the mid-point form of the trapezoidal rule since they engender no numerical damping. This is in contrast to the current practice in dynamic simulations of ground vehicles by employing a set of backward difference formulas. First, the equations of motion are partitioned according to the translational and the rotational coordinates. This sets the stage for an efficient treatment of the rotational motions via the singularity-free Euler parameters. The resulting partitioned equations of motion are then integrated via a two-stage explicit stabilized algorithm for updating both the translational coordinates and angular velocities. Once the angular velocities are obtained, the angular orientations are updated via the mid-point implicit formula employing the Euler parameters. When the two algorithms, namely, the two-stage explicit algorithm for the generalized coordinates and the implicit staggered procedure for the constraint Lagrange multipliers, are brought together in a staggered manner, they constitute a staggered explicit-implicit procedure which is summarized in Section 5. Section 6 presents some example problems and discussions concerning several salient features of the staggered MBD solution procedure are offered in Section 7. Derived from text

FPCAS3D USER'S GUIDE: A THREE DIMENSIONAL FULL POTENTIAL AEROELASTIC PROGRAM, VERSION 1 Final Contractor Report

Milind A. Bakhle Jul. 1995 46 p
(Grant NAG3-1234; RTOP 538-06-14)
(NASA-CR-198367; E-9796; NAS 1.26:198367) Avail: CASI HC A03/MF A01

The FPCAS3D computer code has been developed for aeroelastic stability analysis of bladed disks such as those in fans, compressors, turbines, propellers, or propfans. The aerodynamic analysis used in this code is based on the unsteady three-dimensional full potential equation which is solved for a blade row. The structural analysis is based on a finite-element model for each blade. Detailed explanations of the aerodynamic analysis, the numerical algorithms, and the aeroelastic analysis are not given in this report. This guide can be used to assist in the preparation of the input data required by the FPCAS3D code. A complete description of the input data is provided in this report. In addition, six examples, including inputs and outputs, are provided. Author

A PROBABILISTIC DESIGN METHOD APPLIED TO SMART COMPOSITE STRUCTURES

Michael C. Shiao and Christos C. Chamis (NYMA, Inc., Brook Park, OH.) Aug. 1995 18 p Presented ath the 39th International Symposium and Exhibition, Anaheim, CA, 11-14 Apr. 1994; sponsored by the Society for the Advancement of Materials, and Process Engineering
(Contract NAS3-27186; RTOP 505-62-10)
(NASA-TM-106715; E-9081; NAS 1.15:106715) Avail: CASI HC A03/MF A01

A probabilistic design method is described and demonstrated using a smart composite wing. Probabilistic structural design incorporates naturally occurring uncertainties including those in constituent (fiber/matrix) material properties, fabrication variables, structure geometry and control-related parameters. Probabilistic sensitivity factors are computed to identify those parameters that have a great influence on a specific structural reliability. Two performance criteria are used to demonstrate this design methodology. The first criterion requires that the actuated angle at the wing tip be bounded by upper and lower limits at a specified reliability. The second criterion requires that the probability of ply damage due to random impact load be smaller than an assigned value. When the relationship between reliability improvement and the sensitivity factors is assessed, the results show that a reduction in the scatter of the random variable with the largest sensitivity factor (absolute value) provides the lowest failure probability. An increase in the mean of the random variable with a negative sensitivity factor will reduce the failure probability. Therefore, the design can be improved by controlling or selecting distribution parameters associated with random variables. This can be implemented during the manufacturing process to obtain maximum benefit with minimum alterations. Author

RESIDUAL STRESS DISTRIBUTION IN FeAl WELD OVERLAY ON STEEL

X. L. Wang, S. Spooner, C. R. Hubbard, P. J. Maziasz, G. M. Goodwin, Z. Feng, and T. Zacharia 1994 6 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contract DE-AC05-84OR-21400)
(DE95-009178; CONF-941144-118) Avail: CASI HC A02/MF A01

Neutron diffraction was used to measure the residual stress distribution in an FeAl weld overlay on steel. It was found that the residual stresses accumulated during welding were essentially removed by the post-weld heat treatment that was applied to the specimen; most residual stresses in the specimen developed during cooling following the post-weld heat treatment. The experimental data were compared with a plasto-elastic finite element analysis. While some disagreement exists in absolute strain values, there is satisfactory agreement in strain spatial distribution between the experimental data and the finite element analysis. DOE

SIMULATION OF AIRBORNE ELECTROMAGNETIC MEASUREMENTS IN THREE DIMENSIONAL ENVIRONMENTS

D. L. Alumbaugh and G. A. Newman 1994 11 p Presented at the 8th Annual Symposium on the Application of Geophysics to Environmental and Engineering Problems, Orlando, FL, 23-27 Apr. 1995

(Contract DE-AC04-94AL-85000)

(DE95-008546; SAND-94-2546C; CONF-950450-4) Avail: CASI HC A03/MF A01

A 3-D frequency domain EM modeling code has been implemented for helicopter electromagnetic (HEM) simulations. A vector Helmholtz formulation for the electric fields is employed to avoid problems associated with the first order Maxwell's equations numerically decoupling in the air. Additional stability is introduced by formulating the problem in terms of the scattered electric fields which replaces an impressed dipole source with an equivalent source that possesses a much smoother spatial dependence and is easier to model. In older to compute this equivalent source, a primary field arising from dipole sources in a whole space must be calculated where ever the conductivity is different than that of the background. The Helmholtz equation is approximated using finite differences on a staggered grid. After finite differencing, a complex-symmetric matrix system of equations is assembled and preconditioned using Jacobi scaling before it is solved using the quasi-minimum residual (QMR) method. In order to both speed up the solution and allow for larger, more realistic models to be simulated, the scheme has been modified to run on massively parallel architectures. The solution has been compared against other 1-D and 3-D numerical models and is found to produce results in good agreement. The versatility of the scheme is demonstrated by simulating a survey over a salt water intrusion zone in the Florida Everglades. DOE

COMPUTER VISION FOR DETECTING AND QUANTIFYING GAMMA-RAY SOURCES IN CODED-APERTURE IMAGES

P. C. Schaich, G. A. Clark, S. K. Sengupta, and K. P. Ziock 2 Nov. 1994 10 p Presented at the 28d Annual Asilomar Conference on Signals, Systems, and Computers, Pacific Grove, CA, 31 Oct. - 2 Nov. 1994 Submitted for publication

(Contract W-7405-eng-48)

(DE95-008810; UCRL-JC-117476; CONF-9410156-4) Avail: CASI HC A02/MF A01

The authors report the development of an automatic image analysis system that detects gamma-ray source regions in images obtained from a coded aperture, gamma-ray imager. The number of gamma sources in the image is not known prior to analysis. The system counts the number (K) of gamma sources detected in the image and estimates the lower bound for the probability that the number of sources in the image is K. The system consists of a two-stage pattern classification scheme in which the probabilistic neural network is used in the supervised learning mode. The algorithms were developed and tested using real gamma-ray images from controlled experiments in which the number and location of depleted uranium source disks in the scene are known. DOE

WEATHER INFLUENCE ON PASSIVE MICROWAVE BRIGHTNESS TEMPERATURES

S. M. Loevas, I. Rubinstein, and C. Ulstad Aug. 1994 17 p Prepared in cooperation with Norwegian Hydrodynamic Labs., Trondheim, Norway

(PB95-195384; STF60-S94005) Avail: Issuing Activity (National Technical Information Service (NTIS))

Sea ice charts produced using spaceborne passive microwave observations are used on routine basis at several ice forecasting centers and during sea ice research campaigns. The capability of passive microwave sensors to monitor the earth, regardless of cloud cover or daylight, and the 1400 km swath width (SSM/I) make these sensors well suited not only for ice forecasting but also for providing information needed for planning northern oceanic routes. The retrieval of sea ice parameters is carried out by utilizing 37 and 19 GHz brightness temperatures measured by Special Sensor Microwave Imager (SSM/I) on the Defense Meteorological Satellite Program (DMSP) platform. The ice type identification uses a priori established signature brightness temperatures for each ice type. The algorithm generating the sea ice information contains some climatological information on the weather dependence of the observed brightness temperature. A comparison between passive microwave (SSM/I) retrieved ice parameters and ice maps from the Norwegian Meteorological Institute (DNMI) indicates that the weather correcting procedure within the algorithm may need regionalized input. The correlation of variability of the observed brightness temperatures with the weather changes has to be derived prior to introducing any corrections to the existing algorithms. NTIS

RADIOMETER MEASUREMENTS OF SEA ICE IN THE GULF OF BOTHNIA 1992

L. Kurvonen Sep. 1994 72 p

(PB95-206611; ISBN-951-22-2275-2) Avail: CASI HC A04/MF A01

A helicopter-borne multifrequency radiometer (24, 34, 48 and 94 GHz, vertical polarization) was used to investigate the behavior of the brightness temperature of different sea ice types in the Gulf of Bothnia. The radiometer measurements and their analyses are presented. The measurements were made in dry and wet conditions (air temperature above and below 0 C). The angle of incidence was 45 deg in all measurements. The aim of the study is to determine: (1) frequency dependency of the brightness temperature of different ice types, (2) the capability of the multifrequency radiometer to classify ice types; and (3) the optimum measurement frequencies for mapping sea ice. GEOSTATISTICS AND HYDROLOGY. PART 3. HYDRO-METEOROLOGICAL NETWORK DESIGN

M. J. vanDijk and T. H. M. Rientjes May 1994 37 p

(ISSN 0169-6246)

(PB95-206462; Rept-59-Pt-3) Avail: CASI HC A03/MF A01

At present, the collection of environmental information is increasing in importance. Environmental modeling and defining measures relating to environmental protection policies are usually taken on the basis of the collected information. Hydrological information like precipitation data, runoff data, groundwater table data, piezometric data, etc., is gathered and stored throughout the years by monitoring gaging stations of a (well designed) network. In developing countries, however, gaging stations are often badly spatially distributed, not well managed and often not included in a network. Many water resources management projects are (still) designed with inadequate and incorrect data or even with virtually no data at all. As a consequence of this, it is likely that wrong water management decisions will be taken, the wrong design criteria will be applied, and the inappropriate and uneconomic designs will be developed and operated. The designing of efficient and economic networks is therefore an important issue for hydrologists and civil engineers. The system or network of hydrological gauging stations provides the necessary information to be able to understand and to describe the hydrological phenomena and processes under study. NTIS

(PB95-206470; Rept-56-Pt-1) Avail: CASI HC A03

The various phenomena that are important in hydrology have two important characteristics: they take place in physical space (they manifest themselves in a regionalized form), and each phenomena is known to be unique (i.e. rainfall distribution, soil-moisture content). Those phenomena are all functions of time and space and very often highly variable. A rational framework dealing with spatial variability and uncertainty on the

behavior of phenomena is provided by the theory of random functions. However, the spatial variability is, in general, not random; measured values at two different locations become similar at decreasing distance. In other words, there is some kind of relation in the spatial distribution of these phenomena. Quantities of these phenomena are called 'regionalized variables': they are variables typical of a phenomenon developing in space and possessing a certain structure (here, spatial correlation). The theory of REgionalized Variables (REV's) is based on the theory of random functions, which expresses simultaneously the structured and random character of REV's, as well as mathematical tools necessary for application. The random functions theory covers all possible variabilities, from very low to very high. Its aim is twofold: to establish the theoretical grounds for expressing the structural properties of natural phenomena in a useful mathematical form, and to provide a practical means for solving various problems of estimation. SHIPTRACKS IN THE CALIFORNIAN STRATUS REGION: DEPENDENCY ON MARINE ATMOSPHERIC BOUNDARY LAYER DEPTH M.S. Thesis
Eric J. Trehubenko Dec. 1994 99 p
(AD-A293272) Avail: CASI HC A05/MF A02

Analysis of AVHRR (Advanced Very High Resolution Radiometer) satellite image/atmospheric sounding pairs reveals that the development and persistence of shiptracks is dependent on Marine Atmospheric Boundary Layer Depth (MABL). 65 image/sounding pairs were analyzed with eight cases featured. The data was collected from the SEAHUNT (July 1991) and MAST (June 1994) field experiments off the western coast of the United States. A distribution of cloud-topped MABL's for the dataset reveals that shiptracks developed in boundary layers of depth less than 750 meters. A mean number of shiptracks versus MABL depth reveals that shiptracks decrease in number with increasing boundary layer depth, supporting MAST hypotheses. Several mechanisms are proposed to explain the decrease in track development with increasing MABL depth and these present several avenues for future data analyses. Additionally, a composite track environment is also presented to document other environmental variables encountered during the analysis deemed pertinent to shiptrack formation. DTIC

SATELLITE MULTISENSOR DATA TECHNIQUES FOR SEA ICE MAPPING Final Report
Denise J. Gineris, Douglas A. May, and Jeffrey D. Hawkins 8 Dec. 1994 54 p Limited Reproducibility: Document partially illegible
(AD-A289729; NRL/MR/7240-94-7556) Avail: CASI HC A04/MF A01

Operational sea ice mapping capabilities utilizing ground truth data are extremely limited due to the remote proximity and harsh environment of the polar regions. Satellite remote sensing offers a sufficient quantity of accurate, high resolution environmental parameters that satisfy many ice mapping requirements. This study explores the application of multiple satellite sensor data combination techniques for sea ice analysis. Sea ice information from visible, infrared, passive microwave, and active radar sensors are examined and open water from other ice types in all regions. DTIC

This report summarizes the most relevant information for the project from among the wide range of literature on remote sensing. The facilities offered by IMAGINE have been examined. IMAGINE is a digital image processing package that can store, manipulate, and analyze georeferenced data. It is the most widely used software for remote sensing applications. The other literature cited relates specifically to the aim of the project, i.e. to optimize field sampling from remote images using geostatistics. It includes applications of kriging and spatial filtering to classify remotely sensed date and to enhance the image, the neural net approach, fuzzy classification, sampling images effectively and economically, the use of training data, confidence levels for classification, and the redundancy of information. COMPARISON OF SATELLITE-DERIVED MSU BRIGHTNESS TEMPERATURES AND CONVENTIONALLY-DERIVED FIELDS M.S. Thesis
Matthew C. Parke Dec. 1994 111 p
(AD-A293692) Avail: CASI HC A06/MF A02

A statistical analysis is performed on a six-month global data set consisting of satellite-derived channel 3 Microwave Sounding Unit (MSU) brightness-temperatures from the Marshall Space Flight Center and various conventionally-derived fields obtained from the National Meteorological Center Global Data Assimilation System (GDAS) to quantify the potential usefulness of MSU analyses in the nowcasting and forecasting of baroclinic waves especially over data sparse regions. High positive spatial and temporal correlations are obtained between the MSU and the 400-100 mb thickness over all wavelengths in the data. Slightly lesser positive correlations are found between the MSU and the 200-mb temperature. The MSU-500-mb and MSU-50-mb height correlations indicate a scale dependence in the hydrostatic spreading of thickness anomalies in the vertical. Most significantly, relatively high negative MSU-500-mb height correlations for the short (less than synoptic scale) wavelength portion of the data suggest that upper-level thermal anomalies are reflected downwards and that the MSU can be used to track mid-level synoptic-scale baroclinic waves. This conclusion is also suggested in MSU-500-mb vorticity and MSU-dynamic tropopause correlations. A MSU collection and analysis procedure is also described that demonstrates the practicality and usefulness of generating MSU analyses from locally obtained polar-orbiter data. DTIC

PRODUCING USABLE FUEL FROM MUNICIPAL SOLID WASTE
O. O. Ohlsson 1995 2 p Presented at the Power Generation Conference, Orlando, FL, 7-9 Dec. 1994
(Contract W-31-109-eng-38)
(DE95-008405; ANL/ES/CP-85392; CONF-941210-13) Avail: CASI HC A01/MF A01

Refuse disposal is a matter of increasing concern for municipalities and state governments. As existing land-fills become filled to capacity, and new landfills become more costly to site, it has become critical to develop alternative disposal methods. Some of the refuse that is presently being landfilled has the potential to provide considerable quantities of energy and thereby replace conventional fossil fuels. Another environmental concern is the problem of the emissions associated with combustion of traditional fossil fuels. The Clean Air Act Amendments of 1990 significantly restrict the level of sulfur dioxide (SO2) and nitrogen oxides (NO(x)) emissions permissible as effluent from combustion facilities. To address both of these concerns, Argonne National Laboratory, under sponsorship of the U.S. Department of Energy (DOE), has developed a means of producing fuel from municipal solid waste that can be co-fired with coal to supplement coal supplies and reduce problematic emissions. THE JUNCTION CHARACTERISTICS AND CURRENT CONDUCTION MECHANISMS OF GaInP2 n(+)p DIODES AND SOLAR CELLS Ph.D. Thesis
Kitt C. Reinhardt Dec. 1994 256 p
(AD-A290857; AFIT/WSF/ENP/94-05) Avail: CASI HC A12/MF A03

This work involves an investigation of GaInP2 n+p diode and solar cell dark current mechanisms, the defect centers that affect these mechanisms, and the response of dark current and solar cell photovoltaic parameters to I MeV electron irradiation and thermal annealing. Dark current due to carrier diffusion, recombination, and tunneling were identified, and recombination current was found to dominate at the maximum power-point voltage of the GaInP2 solar cells. Carrier recombination was found to occur via defect centers at the perimeter and within the bulk of the junction. Two deep majority-hole trap centers were found at E(a1) = E(t) - E(v) approximately 0.45 eV and E(a2) = E(t) - E(v) approximately 0.05 eV. Dark current due to carrier tunneling was dominant in 'leaky' diodes and solar cells that contained line-like morphological defects believed to be due to lattice mismatch between GaInP2 and GaAs. The effects of 1 MeV electron irradiation and thermal annealing on solar cell and diode dark current mechanisms and efficiency were also studied. DTIC

STATE-OF-THE-ART LOW-COST SOLAR REFLECTOR MATERIALS
C. Kennedy and G. Jorgensen Nov. 1994 14 p Presented at the 8th International Vacuum Web Coating Conference, Las Vegas, NV, 6-8 Nov.

1994
(Contract DE-AC36-83CH-10093)
(DE95-000260; NREL/TP-471-7022; CONF-9411174-1) Avail: CASI HC A03/MF A01

Solar thermal technologies generate power by concentrating sunlight with large mirrors. The National Renewable Energy Laboratory (NREL) is working with industrial partners to develop the optical reflector materials needed for the successful deployment of this technology. The reflector materials must be low in cost and maintain high specular reflectance for extended lifetimes in severe outdoor environments. Currently, the best candidate materials for solar mirrors are silver-coated low-iron glass and silvered polymer films. Polymer reflectors are lighter in weight, offer greater flexibility in system design, and have the potential for lower cost than glass mirrors. In parallel with collaborative activities, several innovative candidate reflector-material constructions were investigated at NREL. The low-cost material requirement necessitates manufacturing compatible with mass-production techniques. Future cooperative efforts with the web-coating industry offers the promise of exciting new alternative materials and the potential for dramatic cost savings in developing advanced solar reflector materials. SPECTRAL RESPONSE OF A POLYCRYSTALLINE SILICON SOLAR CELL
B. Ba and M. Kane (Dakar Univ., Senegal.) Oct. 1994 12 p
(DE95-614370; IC-94/337) Avail: CASI HC A03/MF A01 (US Sales Only)

A theoretical study of the spectral response of a polycrystalline silicon n-p junction solar cell is presented. The case of a fibrously oriented grain structure, involving grain boundary recombination velocity and grain size effects is discussed. The contribution of the base region on the internal quantum efficiency Q(sub int) is computed for different grain sizes and grain boundary recombination velocities in order to examine their influence. Suggestions are also made for the determination of base diffusion length in polycrystalline silicon solar cells using the spectral response method. DOE

The objective of the Fossil Energy Advanced Research and Technology Development (AR and TD) Materials Program is to conduct research and development on materials for fossil energy applications, with a focus on the longer-term needs for materials with general applicability to the various fossil fuel technologies. The Program includes research aimed at a better understanding of materials behavior in fossil energy environments and on the development of new materials capable of substantial improvement in plant operations and reliability. The scope of the Program addresses materials requirements for all fossil energy systems, including materials for coal preparation, coal liquefaction, coal gasification, heat engines and heat recovery, combustion systems, and fuel cells. Work on the Program is conducted at national and government laboratories, universities, and industrial research facilities. This bibliography covers the period of April 1, 1993, through March 31, 1995, and is a supplement to previous bibliographies in this series. It is the intent of this series of bibliographies to list only those publications that can be conveniently obtained by a researcher through relatively normal channels. The publications listed in this document have been limited to topical reports, open literature publications in referred journals, full-length papers in published proceedings of conferences, full-length papers in unreferred journals, and books and book articles. VALIDATION OF THE FLAGSOL PARABOLIC TROUGH SOLAR POWER PLANT PERFORMANCE MODEL
H. W. Price, P. Svoboda (Flachglas Solartechnick G.m.b.H., Cologne, Germany.), and D. Kearney (Kearney and Associates, Del Mar, CA.) Oct. 1994 6 p Presented at the American Society of Mechanical Engineers/Japanese Society of Mechanical Engineers/Japan Solar Energy Society International Solar Energy Conference, Lahaina, HI, 19-24 Mar. 1995
(Contract DE-AC36-83CH-10093)
(DE95-000263; NREL/TP-471-7297; CONF-950336-19) Avail: CASI HC A02/MF A01

This paper describes the results of a validation of the FLAGSOL parabolic trough solar power plant performance model. The validation was accomplished by simulating an operating solar electric generating system (SEGS) parabolic trough solar thermal power plant and comparing the model output results with actual plant operating data. This comparison includes instantaneous, daily, and annual total solar thermal electric output, gross solar electric generation, and solar mode parasitic electric consumption. The results indicate that the FLAGSOL model adequately predicts the gross solar electric output of an operating plant, both on a daily and an annual basis. DOE

(Contract N00014-94-C-2030)
(AD-A293255) Avail: CASI HC A01/MF A01

Emitter designs have been roughly optimized for both P/N and N/P cells. For P/N cells, the emitter formation and cell junction depth are determined by zinc diffusion from the InGaAs contact cap. Zinc is a P-type dopant in InP. When we attempted to define epitaxially grown emitters, these emitters, which had thickness on the order of 1000 A, were dominated by zinc diffusing out of the InGaAs contact cap, which effectively set the emitter depth at about 3000 A. It therefore made little difference whether the epitaxially grown emitter layer was 100 or 1000 A, since the junction depth was fixed by the zinc diffusing out of the InGaAs to 3000 A. We were able to improve the P/N cell performance by controlling the thickness of the InGaAs cap layer, the solid state diffusion source for the zinc, as well as the growth temperature. Best cell performance was with a 1000 A InGaAs cap thickness with the entire cell grown at 650 C. DTIC

A MANUAL FOR THE ECONOMIC EVALUATION OF ENERGY EFFICIENCY AND RENEWABLE ENERGY TECHNOLOGIES
W. Short, D. J. Packey, and T. Holt Mar. 1995 119 p
(Contract DE-AC36-83CH-10093)
(DE95-000211; NREL/TP-462-5173) Avail: CASI HC A06/MF A02

This manual is a guide for analyzing the economics of energy efficiency and renewable energy (EE) technologies and projects. It is intended: (1) to help analysts determine the appropriate approach or type of analysis and the appropriate level of detail, and (2) to assist EE analysts in completing consistent analyses using standard assumptions and bases, when appropriate. Included are analytical techniques that are commonly required for the economic analysis of EE technologies and projects. The manual consists of six sections: Introduction, Fundamentals, Selection Criteria Guide, Economic Measures, Special Considerations for Conservation and Renewable Energy Systems, and References. A glossary and eight appendices are also included. Each section has a brief introductory statement, a presentation of necessary formulae, a discussion, and when appropriate, examples and descriptions of data and data availability. The objective of an economic analysis is to provide the information needed to make a judgment or a decision. The most complete analysis of an investment in a technology or a project requires the analysis of each year of the life of the investment, taking into account relevant direct costs, indirect and overhead costs, taxes, and returns on investment, plus any externalities, such as environmental impacts, that are relevant to the decision to be

made. However, it is important to consider the purpose and scope of a particular analysis at the outset because this will prescribe the course to follow. The perspective of the analysis is important, often dictating the approach to be used. Also, the ultimate use of the results of an analysis will influence the level of detail undertaken. The decision-making criteria of the potential investor must also be considered. DOE

DATA ON DEVELOPMENT OF NEW ENERGY TECHNOLOGIES
Mar. 1994 296 p In JAPANESE Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE95-764135; NEDO-P-9320) Avail: Issuing Activity (Department of Energy (DOE))

The paper compiles data on the trend of development of new energy technologies into a book. By category, renewable energy is solar energy, wind power generation, geothermal power generation, ocean energy, and biomass. As a category of fuel form conversion, cited are coal liquefaction/gasification, coal gasification combined cycle power generation, and natural gas liquefaction/decarbonization. The other categories are cogeneration by fuel cell and ceramic gas turbine, district heat supply system, power load leveling technology, transportation-use substitution-fuel vehicle, and others (Stirling engine, superconducting power generator, etc.). The data are systematically compiled on essential principles, transition of introduction, objectives of introduction, status of production, cost, development schedule, performance, etc. The paper also deals with the related legislation system, developmental organizations, and a menu for power companies' buying surplus power. DIGITAL SIMULATION OF WIND VELOCITIES FOR WIND TURBINE ROTORS: GENERAL CONSIDERATIONS
J. B. Dragt Dec. 1993 18 p
(PB95-206447; IW-93070R) Avail: CASI HC A03/MF A01

One of the methods to reliably predict the dynamic loads of a wind turbine rotor due to the turbulence of the atmosphere is to simulate the stochastic wind field over the rotor area in a digital way, in order to generate the wind input for a rotor dynamical code. As many points in the rotor area are involved and many time steps, a rather time consuming computation is required. A number of different approaches can be followed, some of which have been realized in practical computer programs, others still have to be explored. This report gives a general overview of simulation methods based on the inverse fast Fourier transform. NTIS

PHOTOVOLTAIC CZOCHRALSKI SILICON MANUFACTURING TECHNOLOGY IMPROVEMENTS Annual Subcontract Report, 1 Apr. 1993 - 31 Mar. 1994
T. Jester (Siemens Solar Industries, Camarillo, CA.) Mar. 1995 19 p Prepared in cooperation with Siemens Solar Industries, Camarillo, CA
(Contract DE-AC36-83CH-10093)
(DE95-004066; NREL/TP-411-7498) Avail: CASI HC A03/MF A01

This report describes work performed under a three-year, three-phase, cost-share contract to demonstrate significant cost reductions and improvements in manufacturing technology. The objective of the program is to reduce costs in photovoltaic manufacturing by approximately 10% per year. The work was focused in three main areas: (1) silicon crystal growth and thin wafer technology; (2) silicon cell processing; and (3) silicon module fabrication and environmental, safety, and health issues. During this reporting period, several significant improvements were achieved. The crystal growing operation improved significantly with an increase in growth capacity due to larger crucibles, higher polysilicon packing density, and high pull speeds. Wafer processing with wire saws progressed rapidly, and the operation is completely converted to wire saw wafer processing. The wire saws yield almost 50% more wafers per inch in production, thus improving manufacturing volume by 50% without any additional expense in crystal growth. Cell processing improvements focused on better understanding the contact paste and firing processes. Module designs for lower material and labor costs began with the focus on a new junction box, larger modules with larger cells, and a less costly framing technique. In addition, chlorofluorocarbon (CFC) usage was completely eliminated in the Siemens manufacturing facility during this period, resulting in significant reductions in the cost of caustic waste treatment. DOE

INVESTIGATION OF POLYCRYSTALLINE THIN FILM CuInSe2 SOLAR CELLS BASED ON ZnSe WINDOWS Annual Subcontract Report, 15 Feb. 1993 - 14 Feb. 1994
L. C. Olsen Mar. 1995 19 p
(Contract DE-AC36-83CH-10093)
(DE95-004068; NREL/TP-413-7684) Avail: CASI HC A03/MF A01

This report concerns studies of CIS solar cells based on ZnSe window layers. ZnSe/CIS devices are fabricated by growing ZnSe films by MOCVD onto Siemens CIS and graded absorber substrates. ZnSe films are grown by reacting H2Se with a zinc adduct. ZnSe/CIS heterojunctions have been studied by depositing transparent aluminum contacts onto ZnSe. These studies indicate that ZnSe/CIS solar cells can be fabricated with an efficiency greater than 14%. Open circuit voltages are typically larger than 500 mV and the optimum range of ZnSe film thickness for maximum efficiency is between 100 Angstrom and 250 Angstrom. Photocurrents are significantly

reduced as the film thickness exceeds 250 Angstrom. Photoluminescence spectroscopy has been utilized to characterize the physical nature of CIS substrate surfaces, and ZnSe-CIS interfaces. These studies indicate that a segregated phase(s) exists at the surface of as received Siemens substrates. Additionally, it is determined that the segregated phase(s) still exist after the ZnSe growth process. To date, sputtered ZnO top contact layers have caused degradation of the photovoltaic properties of the ZnSe/CIS structure. Investigations of the effects of MOCVD grown ZnO upon ZnSe/CIS structures will soon be initiated. To establish the feasibility of ZnSe as a window layer, cells have been fabricated by incorporating a protective layer of CdS between the ZnSe and ZnO. A total area efficiency of 11% was obtained with such a structure. DOE

(Contract DE-AC36-83CH-10093)
(DE95-004063; NREL/TP-412-7680) Avail: CASI HC A09/MF A02

This document provides an overview of the structure and function of typical product certification/laboratory accreditation programs. The overview is followed by a model program which could serve as the basis for a photovoltaic (PV) module certification/laboratory accreditation program. The model covers quality assurance procedures for the testing laboratory and manufacturer, third-party certification and labeling, and testing requirements (performance and reliability). A 30-member Criteria Development Committee was established to guide, review, and reach a majority consensus regarding criteria for a PV certification/laboratory accreditation program. Committee members represented PV manufacturers, end users, standards and codes organizations, and testing laboratories. DOE

LITHIUM ION AQUEOUS CELLS Technical Report, Jul. - Dec. 1994
Edward J. Plichta and Wishvender K. Behl Feb. 1995 19 p
(AD-A293828; ARL-TR-422) Avail: CASI HC A03/MF A01

Lithium ion aqueous cells were investigated using lithium intercalating compounds as anodes and cathodes. The aqueous electrolyte consisted of 4 to 5 molar solutions of either lithium perchlorate or lithium nitrate which contained lithium hydroxide in millimolar amounts to make the solutions slightly basic with a pH of about 8.5. Several electrode combinations were evaluated using lithium intercalating compounds such as lithium cobalt oxide and lithium manganese oxide as cathodes and lithium vanadium oxide, lithium manganese oxide, titanium disulfide, and molybdenum dioxide as the anodes. The cell employing manganese oxide as both the anode and cathode exhibited good charge-discharge characteristics with an open circuit potential of about one volt. DTIC

NaK POOL-BOILER SOLAR RECEIVER DURABILITY BENCH TEST. VOLUME 2: METALLURGICAL ANALYSIS
S. H. Goods and R. W. Bradshaw Jan. 1995 60 p
(Contract DE-AC04-94AL-85000)
(DE95-010338; SAND-94-8235) Avail: CASI HC A04/MF A01

The principal materials used in the construction of a NaK based pool-boiler were analyzed. The device, operated for 7500 hours, accumulated 1000 thermal cycles to a peak temperature of 750 C. Haynes 230, used to fabricate the pool-boiler vessel, was found to perform satisfactorily. Air-side corrosion of the pool-boiler vessel was insignificant. Internal surface of the alloy exhibited some NaK-induced elemental dissolution; this dissolution was somewhat more extensive where the alloy was exposed to the liquid metal compared to regions exposed only to NaK vapor; however, the corresponding metal loss in all regions was inconsequential, never exceeding more than a few microns. Autogenous seam welds of the alloy responded in a similar fashion, exhibiting only minimal metal loss over the course of the experiment. While there was 50% loss in ductility of the alloy there remained adequate ductility for the anticipated operating environment. An enhanced boiling nucleation surface comprised of stainless steel powder brazed to the vessel ID showed no change in its structure. It remained intact, showing no cracking after repeated thermal cycling. Other materials used in the experiment showed more extensive degradation after exposure to the NaK. IN 600, used to fabricate thermowells, exhibited extensive surface and intergranular dissolution. Grain boundary dissolution was sufficiently severe in one of the thermowells to cause an air leak, resulting in experiment termination. BNi-3, a brazing alloy used to join the pool-boiler vessel, endcaps and thermowells, showed some dissolution where it was exposed to the NaK as well as thermal aging effects. However, all brazes remained structurally sound. A nickel metal ribbon showed catastrophic dissolution, resulting in the formation of deep (greater than 30 (mu)m) pits and cavities. A zirconium metal foil used to getter oxygen from the NaK became extremely brittle. DOE

STUDY OF MELTING AND FREEZING PROCESSES OF WATER FOR APPLICATION TO ICE THERMAL ENERGY STORAGE SYSTEM Ph.D. Thesis
Liang Yong 1993 150 p
Avail: Univ. Microfilms Order No. DA9414040

This thesis presents the results of a study of the solid-liquid phase change process of water in a rectangular enclosure for application to thermal energy storage systems. The work performed combined experimental results with analytical and numerical methods to develop computer models of the system. Experiments were performed to obtain data to verify the models under various melting and freezing conditions. A connective heat transfer correlation, for melting of ice in a container confined by two horizontal plates, was obtained based on the experimental work. An analytical model based on heat conduction was developed to predict ice formation in an enclosure which was cooled isothermally. A model incorporating the effects of convection, conduction, and buoyancy was developed to predict the solid-liquid interface position and melting rate for the melting of unfixed ice in the enclosure which was heated isothermally. Comparisons were made between the models and the experiment data. The results demonstrated satisfactory agreement. Finally, a preliminary model was developed to predict the overall performance of melting in a cool thermal energy storage system. The results of the model were used to produce design criteria for thermal energy storage systems. Dissert. Abstr.

BIOFACTS: FUELING A STRONGER ECONOMY, THERMOCHEMICAL CONVERSION OF BIOMASS
Dec. 1994 4 p
(Contract DE-AC36-83CH-10093)
(DE94-006866; NREL/SP-420-6379) Avail: CASI HC A01/MF A01

A primary mission of the US DOE is to stimulate the development, acceptance, and use of transportation fuels made from plants and wastes called biomass. Through the National Renewable Energy Laboratory (NREL), DOE is developing and array of biomass conversion technologies that can be easily integrated into existing fuel production and distribution systems. The variety of technology options being developed should enable individual fuel producers to select and implement the most cost-effective biomass conversion process suited to their individual needs. Current DOE biofuels research focuses on the separate and tandem uses of biochemical and thermochemical conversion processes. This overview specifically addresses NREL's thermochemical conversion technologies, which are largely based on existing refining processes. DOE

N95-31952 Clarkson Univ., Potsdam, NY.
SILICON CARBIDE-SILICON HETEROSTRUCTURE SOLAR CELLS Ph.D.

Thesis
Attaullah Solangi 1994 104 p
Avail: Univ. Microfilms Order No. DA9422827

Silicon Carbide/Silicon/Silicon (SiC/Si/Si) (N-n-p) heteroface solar cells are designed, fabricated, and evaluated. In these solar cells the top SiC layer, which is transparent to most of the solar spectrum, yields a low lateral resistance and passivates the surface of the n-Si layer. Processes are developed to fabricate SiC/Si heterostructure solar cells. SiC films are grown on (100) Si substrates using an Atmospheric Pressure Chemical Vapor Deposition (APCVD) technique. Hydrogen, Silane (SiH4), and Propane (C3H8) serve as a carrier gas, Silicon and Carbon source gases, respectively. A process is developed to in situ dope single crystal Silicon Carbide (beta-SiC) films using phosphine (PH3). The beta-SiC films are characterized using x-ray Diffractometer and four-point probe. Optical studies show that the absorption coefficient of ,19-SiC films increases with increase in doping level and ranges from 10 to 6 x 10(exp 4) cm(exp -1) in the energy range between 2.42 and 4.4 eV. The bandgap of beta-SiC films ranges between 2.13 and 2.32 eV. APCVD grown films in the 1150 deg C and 1200 deg C temperature range are single crystal beta-SiC and show the doping effect. The sheet resistance (r(sub s)) value of the in situ doped beta-SiC films ranges from 90 to 500 Omega/(square). The r(sub s) becomes smaller at higher growth temperature and higher PH3 flow rate. The lowest r(sub s) value achieved is 90 Omega/(square). A computer analysis of the heterostructure and homojunction Si solar cells, based on the drift-diffusion model, is carried out. It is noted that employing a SiC layer as a top window material in Si-based solar cells reduces the series resistance of the cell and increases the efficiency. Also, the light generated current in the SiC/Si cells does not decrease appreciably with increasing thickness of the top SiC layer. In contrast, in Si/Si cells the current reduces significantly with increasing thickness of the top Si layer. The Si-based heterostructure solar cells (with beta-SiC as the top window material) are designed and fabricated. At AM 1.5 solar radiation these cells exhibit the following typical characteristics: V(sub oc) = 540 mV, J(sub sc) = 27.66 mA/sq cm, FF = 76 percent, Efficiency = 11.36 percent, while similar Si homojunction solar cells made from the same Si substrate show inferior characteristics. This study shows that the SiC/Si is a potentially useful system for fabricating high efficiency Si-based solar cells. Dissert. Abstr.

DEVELOPMENT OF LARGE-AREA MONOLITHICALLY INTEGRATED SILICON-FILM(TRADEMARK) PHOTOVOLTAIC MODULES Final Subcontract Report, 1 May 1991 - 31 Dec. 1994
R. B. Hall, J. A. Rand, and J. E. Cotter Apr. 1995 27 p
(Contract DE-AC36-83CH-10093)
(DE95-004089; NREL/TP-413-7702) Avail: CASI HC A03/MF A01

The objective of this program is to develop Silicon Film(trademark) Product-3 into a low-cost, stable solar cell for large-scale terrestrial power applications. The Product-3 structure is a thin (less than 100 micro m) polycrystalline layer of silicon on a durable, insulating, ceramic substrate. The insulating substrate allows the silicon layer to be isolated and metallized to form a monolithically interconnected array of solar cells. High efficiency is achieved by the use of light trapping and passivated surfaces. This project focused on the development of five key technologies associated with the monolithic sub-module device structure: (1) development of the film deposition and growth processes; (2) development of the low-cost ceramic substrate; (3) development of a metallurgical barrier technology; (4) development of sub-element solar cell processing techniques; and (5) development of sub-module (isolation and interconnection) processes. This report covers the development approaches and results relating to these technologies. Significant progress has been made in the development of all of the related technologies. This is evidenced by the fabrication of a working 12.0 sq cm prototype sub-module consisting of 7 elements and testing with an open circuit voltage of 3.9 volts, a short circuit current of 35.2 mA and a fill factor of 63% and an overall efficiency of 7.3%. Another significant result achieved is a 13.4% (NREL verified), 1.0 sq cm solar cell fabricated from material deposited and grown on a graphite cloth substrate. The significant technological hurdle of the program was and remains the low quality of the photovoltaic layer which is caused by contamination of the photovoltaic layer from the low-cost ceramic substrate by trace impurities found in the substrate precursor materials. The ceramic substrate and metallurgical barrier are being developed specifically to solve this problem. DOE

Mar. 1994 235 p In JAPANESE
(DE95-769806; NEDO-P-9327) Avail: CASI HC A11/MF A03

A detailed study is made on introduction of the photovoltaic power generation system to Japan. The paper analyzes influences of production learning of the equipment, fund subsidies and overseas export production on wide spread of the photovoltaic power generation system, and clarifies the potential amount of the future introduction. The analysis is conducted by converting learning coefficients of battery cell and inverter to 0.7, 0.8 (standard), and 0.9. The cumulative spread of the system by 2040 will amount to 14,911MW, 819MW (standard), 117MW, respectively. The future introduction amount is analyzed by changing exports of the photovoltaic power generation. The cumulative spread of the system by 2040 will increase up to 2,015MW in case of 6% as against 819MW in standard case of 3%. If changing the rate of fund subsidies to 50% (standard), 67% and 75%, the cumulative spread amount will be 819MW (standard), 6,257MW and 10,173MW, and reduction of CO2 emissions will be 1 million t-c/yr, 2 million t-c/yr and 3 million t-c/yr, respectively. DOE

ENERGY STORAGE AND ALTERNATIVES TO IMPROVE TRAIN VOLTAGE ON A MASS TRANSIT SYSTEM
S. P. Gordon and W. S. Rorke Apr. 1995 66 p
(Contract DE-AC04-94AL-85000)
(DE95-010344; SAND-95-8222) Avail: CASI HC A04/MF A01

The wide separation of substations in the Bay Area Rapid Transit system's transbay tunnel contributes to voltage sag when power demand is high. In the future, expansions to the system will exacerbate this problem by increasing traffic density. Typically, this situation is remedied through the installation of additional substations to increase the system's power capacity. We have evaluated the efficacy of several alternatives to this approach - specifically, installation of an 8 megajoule energy storage system, modification of the existing substations, or reduction of the resistance of the running rails or the third rail. To support this analysis, we have developed a simple model of the traction power system in the tunnel. We have concluded that the storage system does not have sufficient capacity to deal with the expected voltage sags; in this application, the alternatives present more effective solutions. We have also investigated the potential impact of these system upgrades on expected future capital outlays by BART for traction power infrastructure additions. We have found that rail or substation upgrades may reduce the need for additional substations. These upgrades may also be effective on other parts of the BART system and on other traction power systems. DOE

INVESTIGATION OF THE BASIC PHYSICS OF HIGH EFFICIENCY SEMICONDUCTOR HOT CARRIER SOLAR CELL Annual Status Report, 31 May 1994 - 30 May 1995
R. R. Alfano, W. B. Wang, J. M. Mohaidat, M. A. Cavicchia, and O. Y. Raisky 30 May 1995 17 p
(Grant NAG3-1490)
(NASA-CR-198945; NAS 1.26:198945) Avail: CASI HC A03/MF A01

The main purpose of this research program is to investigate potential semiconductor materials and their multi-band-gap MQW (multiple quantum wells) structures for high efficiency solar cells for aerospace and commercial applications. The absorption and PL (photoluminescence) spectra, the carrier dynamics, and band structures have been investigated for semiconductors

of InP, GaP, GaInP, and InGaAsP/InP MQW structures, and for semiconductors of GaAs and AlGaAs by previous measurements. The barrier potential design criteria for achieving maximum energy conversion efficiency, and the resonant tunneling time as a function of barrier width in high efficiency MQW solar cell structures have also been investigated in the first two years. Based on previous carrier dynamics measurements and the time-dependent short circuit current density calculations, an InAs/InGaAs - InGaAs/GaAs - GaAs/AlGaAs MQW solar cell structure with 15 bandgaps has been designed. The absorption and PL spectra in InGaAsP/InP bulk and MQW structures were measured at room temperature and 77 K with different pump wavelength and intensity, to search for resonant states that may affect the solar cell activities. Time-resolved IR absorption for InGaAsP/InP bulk and MQW structures has been measured by femtosecond visible-pump and IR-probe absorption spectroscopy. This, with the absorption and PL measurements, will be helpful to understand the basic physics and device performance in multi-bandgap InAs/InGaAs - InGaAs/InP - InP/InGaP MQW solar cells. In particular, the lifetime of the photoexcited hot electrons is an important parameter for the device operation of InGaAsP/InP MQW solar cells working in the resonant tunneling conditions. Lastly, time evolution of the hot electron relaxation in GaAs has been measured in the temperature range of 4 K through 288 K using femtosecond pump-IR-probe absorption technique. The temperature dependence of the hot electron relaxation time in the X valley has been measured. Derived from text

PRODUCTION SIMULATOR FOR WAVE POWER PLANTS
K. Torsethaugen 7 Jul. 1994 25 p
(PB95-212262; STF60-A94094) Avail: Issuing Activity (National Technical Information Service (NTIS))

The report gives plans and specifications for a wave power production simulator. The simulator is a computer program that computes how much of the energy in the open ocean that can be converted to usable energy at a site off or onshore. The production of wave power from sea waves is not an easy task. Efforts have been made in several countries to develop devices that can extract energy from the ocean, but very few have so far been successful. During the last 15 years a considerable know-how has been established in Norway on wave energy utilization. Part of this know-how will be included in the proposed production simulator. Evaluation of new devices and new sites can be done in a more comparative and efficient way by this tool. It will contribute to interdisciplinary activity in the field of wave power utilization, and should be applicable for the nonexpert. The simulator consists of several modules, joined together by computer software. The plans so far include purpose, needs and background for the development of a wave power plant simulator and a high level specification of the software and scope of work. NTIS

EXTRA FOCAL CONVECTIVE SUPPRESSING SOLAR COLLECTOR Second Quarterly Technical Progress Report
1995 4 p
(Contract DE-FG01-94CE-15601)
(DE95-010170; DOE/CE-15601/T1) Avail: CASI HC A01/MF A01

Second quarter efforts have focused on completing Task 1, refining and improving tracking electronics, and working on Tasks 2 and 3, optics and absorber/fluid system, respectively. Calculated collector performance for various configurations based on collector component manufacturers product data lead to the following conclusions: (1) all loss mechanisms are proportional to the absorber area; (2) for sufficiently high concentration ratios, at the temperatures that are significant for residential applications, the reduced convective losses at the absorber associated with a transparent cover are partially offset by the reduced transmission, and therefore energy input, of the cover; (3) radiative losses are most effectively reduced by use of a spectrally-selective absorber and minimizing the absorber area; (4) for a concentrating system operating at a temperature useful for residential applications (above 60 C, probably around 100 C), the ambient temperature (range: -30 C to +30 C) makes relatively little difference in the collectible power; and (5) on account of the first conclusion, the most cost-effective system will have a concentration ratio as high as cost-effectively possible. OUTLOOK FOR RENEWABLE ENERGY TECHNOLOGIES: ASSESSMENT OF INTERNATIONAL PROGRAMS AND POLICIES
Linda J. Branstetter, Richard C. Vidal, Vicki L. Bruch, and Rena Zurn Feb. 1995 112 p
(Contract DE-AC04-94AL-85000)
(DE95-009084; SAND-94-0854) Avail: CASI HC A06/MF A02

The report presents an evaluation of worldwide research efforts in three specific renewable energy technologies, with a view towards future United States (US) energy security, environmental factors, and industrial competitiveness. The overall energy technology priorities of foreign governments and industry leaders, as well as the motivating factors for these priorities, are identified and evaluated from both technological and policy perspectives. The specific technologies of interest are wind, solar thermal, and solar photovoltaics (PV). These program areas, as well as the overall energy policies of Denmark, France, Germany, Italy, the United Kingdom (UK), Japan, Russia, and the European Community as a whole are described. The present and likely future picture for worldwide technological leadership in these technologies is portrayed. The report is meant to help in forecasting challenges to US preeminence in the various technology areas, particularly over the next ten years, and to help guide US policy-makers as they try to identify specific actions which would help to retain and/or expand the US leadership position. NATIONAL INSTITUTE FOR GLOBAL ENVIRONMENTAL CHANGE Final Report
W. R. Cotton, B. Stevens, D. Duda, W. Richardson, and G. Feingold Mar. 1995 44 p Prepared in cooperation with National Inst. for Global Environmental Change Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-FC03-90ER-61010)
(DE95-008333; DOE/ER-61010/T27) Avail: CASI HC A03

Over the past decade or so the evolution and equilibria of persistent decks of stratocumulus climatologically clinging to the edge of summertime subtropical highs has been an issue of increased scientific inquiry. The particular interest in the microphysical structure of these clouds stems from a variety of hypotheses which suggest that anthropogenic influences or biogenic feedbacks may alter the structure of these clouds in a manner which may be climatically significant. Most hypotheses regarding boundary layer influences on climate have been formulated by an examination of the solution space of simple models. The earliest hypothesis of this sort (and the one on the most solid footing) is due to Twomey (1974), who posited that enhanced concentrations of CCN could lead to enhanced droplet reflectivity and enhanced albedos in clouds of modest optical depths. In low lying clouds where the albedo effect dominates, the climate sensitivity to a robust perturbation in cloud albedo may be significant. One of the primary objectives of this current research has been to explore the hypothesis of Twomey. The basic approach was to couple radiative calculations with detailed representations of the droplet spectra. The detailed representation of the droplet spectra was generated by the Large Eddy Simulation-Explicit

Microphysics (LES-EM) model coupled to a simple mixed emissivity radiation scheme in order to drive the dynamics. Several simulations were carried out and the resultant microphysical fields were taken from the stationary regime of the turbulent simulation and used to drive a two dimensional radiative model. By comparing the radiative properties of the simulated clouds formed in environments with different CCN concentrations we were able to more accurately quantify the albedo susceptibility of stratocumulus taken to be typical of the FIRE experimental area. ECONOMICAL ANALYSIS RELATING TO THE GLOBAL WARMING ISSUE
Aug. 1994 220 p
(DE95-764072; IEE-SR-257) Avail: CASI HC A10/MF A03

An analysis using global macro economic models is conducted on how to think and cope with the global warming issue from political and economic aspects. As viewpoints of evaluation, cited are cost estimation for the CO2 emission control, damage caused by the global warming and its economic evaluation, and the catastrophic effects on the ecosystem except the economic evaluation. Cline says that maximum efforts should be exerted to suppress CO2 emission to the level of 1990 by the year of 2000. It is said that to confirm how serious greenhouse effects will be in 2000, it is necessary to concentrate on scientific researches, and that the international society should make its second-stage determination in terms of freezing or reducing the level of 2000, or admitting that the level will go upward. For this, the economic distortion should be removed by removing assistance to fossil fuels step by step. Assistance to developing countries and economical efficiency should be raised by introducing the carbon tax. Improvement of efficiency and arrangement of incentives are required for individual technologies. Measures for forest preservation are necessary under the financial assistance program, etc. DOE

THE LAND COMPONENT OF THE GLOBAL CLIMATE SYSTEM WITH ADEQUATE SPATIAL RESOLUTION Final Report, 1 Sep. 1991 - - 31 Aug. 1994
R. E. Dickinson, A. N. Hahmann, X. Zeng, M. Chen, J. Vaughan, and B. A. Auvine 30 Nov. 1994 58 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(Contract DE-FG02-91ER-61216)
(DE95-009323; DOE/ER-61216/3) Avail: CASI HC A04

The focus of the work done under this grant has been to couple global circulation models (in particular, the National Center for Atmospheric Research (NCAR) Community Climate Model Version 2 (CCM2)) to a land-surface model at a much finer mesh than that used for the atmospheric processes. The end objective has been to incorporate into the CHAMMP modeling system a state-of-the-art land model on a mesh independent of the atmospheric model resolution. Efforts have emphasized the following: development and graphical displays of the fine-mesh land surface boundary conditions; the data structures required to carry out integrations on the land fine-mesh; the physical parameterization required to diaggregate model precipitation; analyses of the NCAR 10-year control simulation of the frozen version of CM2/BATS; implementation of changes in the cloud optical properties to mitgate excess incident solar radiation and temperatures over middle latitudes in the Northern Hemisphere summer; prototype development of the CCM2/BASTS fine-mesh treatment. GLOBAL CHANGE RESEARCH: SUMMARIES OF RESEARCH IN FY 1994
Apr. 1994 236 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE95-009660; DOE/ER-0641T) Avail: Issuing Activity (Department of Energy (DOE))

Global climate change is a significant issue for DOE because energy production and use now contributes more than half of the total human emissions of greenhouse gases on a global basis. Within the DOE Global Change Research Program, we are proceeding with the transition from the carbon-cycle and vegetation-research programs to a reconfigured and integrated program on terrestrial carbon processes. The overall objective is to increase our knowledge and understanding of the role of terrestrial components in the global carbon cycle with special reference to biological controls on atmospheric carbon dioxide concentration. The primary objective of DOE's global-change program remains the improved prediction of global change as a basis for sustainable development. This publication describes all of the projects funded by the Environmental Sciences Division of DOE in FY 1994. Each description contains the project's title; its 3-year funding history; the period over which the funding applies; the name of the principal investigator(s); the institution(s) conducting the projects; and the project's objectives, products, approach, and results to date. FIELD PERFORMANCE OF THE WALKER BRANCH THROUGHFALL DISPLACEMENT EXPERIMENT
P. J. Hanson, D. E. Todd, N. T. Edwards, and M. A. Huston Oct. 1994 12 p Presented at the International Symposium On Ecosystem Manipulation, Bowness-on-Windermere, UK, 19-21 Oct. 1994
(Contract DE-AC05-84OR-21400)
(DE95-008677; CONF-9410327-1) Avail: CASI HC A03/MF A01

The authors are conducting a large-scale manipulative field experiment in an upland oak forest on the Walker Branch Watershed in eastern Tennessee USA to identify important ecosystem responses that might result from future precipitation changes. The manipulation of soil moisture is being implemented by a gravity-driven transfer of throughfall precipitation from one treatment plot to another. Throughfall is intercepted in (approx) 2,000 subcanopy troughs (0.3 x 5 m) suspended above the forest floor of the dry plots ((approx) 33% of the ground area is covered) and transferred by gravity flow across an ambient plot for subsequent distribution onto the wet treatment plot. Percent soil water is being monitored with time domain reflectometers at 310 sampling locations across the site. The experimental system is able to produce statistically significant differences in soil water content in years having both extremely dry and extremely wet conditions. Furthermore, comparisons of pre- and post-installation soil temperature measurements have documented the ability of the experimental design to produce these changes without changing the microclimate of the forest understory. HISTORY AND STATUS OF THE ATMOSPHERIC RADIATION MEASUREMENT PROGRAM
P. Lunn, T. Cress (Pacific Northwest Lab., Richland, WA.), and G. Stokes (Pacific Northwest Lab., Richland, WA.) Apr. 1995 373 p Presented at the Atmospheric Radiation Measurement Science Team Meeting, Charleston, SC, 28 Feb. - 3 Mar. 1994 Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(DE95-009951; CONF-940277) Avail: CASI HC A16

This document contains the summaries of papers presented at the 1994 Atmospheric Radiation Measurement (ARM) Science Team meeting held in Charleston, South Carolina. To put these papers in context, it is useful to consider the history and status of the ARM Program at the time of the meeting. The history of the project has several themes. First, the program has from its very beginning attempted to respond to most critical scientific issues facing the United States Global Change Research Program. Second, the program has been strongly coupled to other agency and international programs. The program reflects an unprecedented collaboration among the various elements of the national research community, including a significant level of cooperation among the U.S. Department of Energy's (DOE) national laboratories. Next, ARM has always attempted to make the most judicious use of its resources by collaborating and leveraging existing assets and has managed to maintain an aggressive schedule despite budgets that have been much smaller than planned. Finally, the program has attracted some of the very best scientific talent in the climate research community and has, as a result, been very productive scientifically. An introduction covers the first three points; the papers themselves speak to the last point. DOE

SPATIAL TIME-SERIES: POLLUTION PATTERN RECOGNITION UNDER IRREGULAR INTERVENTIONS M.S. Thesis

Samuel A. Wright Mar. 1995 191 p

(AD-A293830; AFIT/GOR/ENS/95M-19) Avail: CASI HC A09/MF A02

The Fernald Environmental Restoration Management Corporation (FERMCO) has noted the introduction of arsenic contamination to groundwater around the area of the groundwater recovery system, which captures uranium contaminated groundwater. The introduction of arsenic occurs during high levels of pumping and is particularly sensitive to the western two of the five pumps. Auto-Regressive Moving Average (ARMA) and Spatial-Temporal ARMA (STARMA) empirical analyses are used to model the level of arsenic contamination found through time. The intervention of varied levels of pumping is modeled with a transfer function using analytic techniques to create a causal intervention transfer function input series to give physical meaning to the impulse response weights found. Spatial weights employed in the STARMA modeling are also created using analytic, causal methods. Results suggest a physical interpretation of the relationship between a particular level of pumping and the amount of arsenic to be found at the site in the temporal case, while including the effect of the pumping on a site of interest's neighbors in the spatial-temporal case. Models presented may be employed in the forecasting of arsenic levels at monitoring well sites due to a given change in the operation level of the groundwater recovery system. DTIC

BIOMASS PRODUCTION BY FESCUE AND SWITCHGRASS ALONE AND IN MIXED SWARDS WITH LEGUMES Final Project Report

Michael Collins Jun. 1994 101 p Prepared in cooperation with Kentucky Univ., Lexington, KY

(Contract DE-AC05-84OR-21400)

(DE95-009137; ORNL/Sub-88-SC617) Avail: CASI HC A06/MF A02

In assessing the role of biomass in alleviating potential global warming, the absence of information on the sustainability of biomass production on soils of limited agricultural potential is cited as a major constraint to the assessment of the role of biomass. Research on the sustainability of yields, recycling of nutrients, and emphasis on reduced inputs of agricultural chemicals in the production of biomass are among the critical research needs to clarify optimum cropping practice in biomass production. Two field experiments were conducted between 1989 and 1993. One study evaluated biomass production and composition of switchgrass (Panicum virgatum L.) grown alone and with bigflower vetch (Vicia grandiflora L.) and the other assessed biomass productivity and composition of tall fescue (Festuca arundinacea Schreb.) grown alone and with perennial legumes. Switchgrass received 0, 75 or 150 kg/ha of N annually as NH4NO3 or was interseeded with vetch. Tall fescue received 0, 75, 150 or 225 kg/ha of N annually or was interseeded with alfalfa (Medicago L.) or birdsfoot trefoil (Lotus corniculatus L.). It is hoped that production systems can be designed to produce high yields of biomass with minimal inputs of fertilizer N. Achievement of this goal would reduce the potential for movement of NO3 and other undesirable N forms outside t he biomass production system into the environment. In addition, management systems involving legumes could reduce the cost of biomass production. DOE

ENVIRONMENTAL PROJECTS. VOLUME 16: WASTE MINIMIZATION ASSESSMENT

15 Dec. 1994 73 p

(Contract NAS7-1260; RTOP 314-40-32-10-23)

(NASA-CR-198861; JPL-Publ-87-4-Vol-16; NAS 1.26:198861) Avail: CASI HC A04/MF A01

The Goldstone Deep Space Communications Complex (GDSCC), located in the MoJave Desert, is part of the National Aeronautics and Space Administration's (NASA's) Deep Space Network (DSN), the world's largest and most sensitive scientific telecommunications and radio navigation network. The Goldstone Complex is operated for NASA by the Jet Propulsion Laboratory. At present, activities at the GDSCC support the operation of nine parabolic dish antennas situated at five separate locations known as 'sites.' Each of the five sites at the GDSCC has one or more antennas, called 'Deep Space Stations' (DSS's). In the course of operation of these DSS's, various hazardous and non-hazardous wastes are generated. In 1992, JPL retained Kleinfelder, Inc., San Diego, California, to quantify the various streams of hazardous and non-hazardous wastes generated at the GDSCC. In June 1992, Kleinfelder, Inc., submitted a report to JPL entitled 'Waste Minimization Assessment.' This present volume is a JPL-expanded version of the Kleinfelder, Inc. report. The 'Waste Minimization Assessment' report did not find any deficiencies in the various waste-management programs now practiced at the GDSCC, and it found that these programs are being carried out in accordance with environmental rules and regulations. PARTICULATE AIR POLLUTION AND INCREASED MORTALITY: BIOLOGICAL PLAUSIBILITY FOR CAUSAL RELATIONSHIP

R. F. Henderson 1995 8 p Presented at the Air and Waste Management Association Meeting, San Antonio, TX, 18-23 Jun. 1995

(Contract DE-AC04-76EV-01013)

(DE95-006161; CONF-950646-1) Avail: CASI HC A02/MF A01

Recently, a number of epidemiological studies have concluded that ambient particulate exposure is associated with increased mortality and morbidity at PM concentrations well below those previously thought to affect human health. These studies have been conducted in several different geographical locations and have involved a range of populations. While the consistency of the findings and the presence of an apparent concentration response relationship provide a strong argument for causality, epidemiological studies can only conclude this based upon inference from statistical associations. The biological plausibility of a causal relationship between low concentrations of PM and daily mortality and morbidity rates is neither intuitively obvious nor expected based on past experimental studies on the toxicity of inhaled particles. Chronic toxicity from inhaled, poorly soluble particles has been observed based on the slow accumulation of large lung burdens of particles, not on small daily fluctuations in PM levels. Acute toxicity from inhaled particles is associated mainly with acidic particles and is observed at much higher concentrations than those observed in the epidemiology studies reporting an association between PM concentrations and morbidity/mortality. To approach the difficult problem of determining if the association between PM concentrations and daily morbidity and mortality is biologically plausible and causal, one must consider (1) the chemical and physical characteristics of the particles in the inhaled atmospheres, (2) the characteristics of the morbidity/mortality observed and the people who are affected, and (3) potential mechanisms that might link the two. THE ROLE OF THE HYDROLOGICAL CYCLE AND THE OCEAN'S THERMOHALINE CIRCULATION IN CLIMATE CHANGE: A

MULTICOMPONENT CLIMATE MODEL STUDY Ph.D. Thesis
Huaxiao Wang 1993 132 p
Avail: Univ. Microfilms Order No. DA9415831

Global ocean-atmosphere and ocean-atmosphere-continental ice sheet models are developed to address the question of feedbacks between the hydrological cycle and the global thermohaline circulation capable of explaining the climate changes seen in paleoclimate records of the late Pleistocene and the last deglaciation. The ocean-atmosphere model climate system displays two distinct stable equilibria controlled by latitudinal water vapor transport and the net flux of water vapor from the Atlantic to the Pacific Ocean. If the inter-basin transport is sufficiently large, small changes in water vapor transport over the North Atlantic can effect bifurcation; maximum difference between the modes occurs in the North Atlantic. If the inter-basin transport is from the Pacific to the Atlantic and sufficiently large, latitudinal vapor transport in the North Pacific controls the bifurcations, with maximum changes occurring in the North Pacific. For intermediate values of inter-basin transport, no rapid transitions occur in either basin. In the regime with vapor flux from the Atlantic to the Pacific, one mode has strong production of deep water in the North Atlantic and a large flux of heat to the atmosphere from the high latitude North Atlantic. The other has strong deep water production in the Southern Ocean and weak production in the North Pacific and small heat transport to high-latitude North Atlantic. The ocean-atmosphere-ice sheet system displays feedbacks which produce century/millennium time scale oscillations. The thermohaline circulation plays a central role in these feedbacks because of its transport of both heat and salt. The feedbacks could potentially play a causal role in the century/milliennium climate change seen in the paleoclimate record. Dissert. Abstr.

BIOFACTS: FUELING A STRONGER ECONOMY, GLOBAL WARMING AND BIOFUELS EMISSIONS
Dec. 1994 4 p
(Contract DE-AC36-83CH-10093)
(DE94-006864; NREL/SP-420-6365) Avail: CASI HC A01/MF A01

The focus of numerous federal and state regulations being proposed and approved today is the reduction of automobile emissions, particularly carbon dioxide (CO2), which is the greenhouse gas considered responsible for global warming. Studies conducted by the US DOE through the National Renewable Energy Laboratory (NREL) indicate that the production and use of biofuels such as biodiesel, ethanol, and methanol could nearly eliminate the contribution of net CO2 from automobiles. This fact sheet provides an overview of global warming, followed by a summary of NREL's study results. DOE

THE GCRC TWO-DIMENSIONAL ZONALLY AVERAGED STATISTICAL DYNAMICAL CLIMATE MODEL: DEVELOPMENT, MODEL PERFORMANCE, AND CLIMATE SENSITIVITY Ph.D. Thesis
Robert Malcolm MacKay 1994 273 p
Avail: Univ. Microfilms Order No. DA9415946

The two-dimensional statistical dynamical climate model that has recently been developed at the Global Change Research Center and the Oregon Graduate Institute of Science & Technology (GCRC 2D climate model) is presented and several new results obtained using the model are discussed. The model solves the 2-D primitive equations in finite difference form (mass continuity, Newton's second law, and the first law of thermodynamics) for the prognostic variables zonal mean density, zonal mean zonal velocity, zonal mean meridional velocity, and zonal mean temperature on a grid that has 18 nodes in latitude and 9 vertical nodes (plus the surface). The equation of state, p = (rho RT) and an assumed hydrostatic atmosphere, Delta(p) = -(rho g Delta z) are used to diagnostically calculate the zonal mean pressure and vertical velocity for each grid node, and the moisture balance equation is used to estimate the precipitation rate. The performance of the model at simulating the two-dimensional temperature, zonal winds, and mass stream function is explored. The strengths and weaknesses of the model are highlighted and suggestions for future model improvements are given. The parameterization of the transient eddy fluxes of heat and momentum developed by Stone and Yao (1987 and 1990) are used with small modifications. These modifications are shown to help the performance of the model at simulating the observed climate system as well as increase the model's computational stability. Following earlier world that analyzed the response of the zonal wind fields predicted by three GCM simulations for a doubling of atmospheric CO2, the response of the GCRC 2D model's zonal wind fields is also explored for the same experiment. Unlike the GCM simulations, our 2D model results in distinct patterns of change. It is suggested that the observed changes in zonal winds for the 2xCO2 experiment are related to the increase in the upper level temperature gradients predicted by our model and most climate models of adequate sophistication and resolution. We thus suggest that the same mechanism controlling the changes in zonal winds for the 2xCO2 experiment in our model also contributes to the simulated changes in zonal winds of the more complex GCM's. Dissert. Abstr.

GLOBAL CLIMATOLOGY AND VARIABILITY OF POTENTIAL NEW PRODUCTION ESTIMATED FROM REMOTE SENSING OF SEA-SURFACE TEMPERATURE Final Report, 1 May 1992 - 30 Apr. 1995
Richard C. Dugdale and Frances P. Wilkerson 30 Apr. 1995 13 p
(Grant NAGw-3149)
(NASA-CR-198840; NAS 1.26:198840; NRA-91-OSSA-07) Avail: CASI HC A03/MF A01

During this project we have collected numerous shipboard data-bases of oceanic nitrate and silicate versus temperature for both equatorial and coastal upwelling regions. These cruises all have accompanying N-15 measurements of new production. The inverse relationships between nutrients and temperatures have been determined and are being used to obtain surface nutrient fields from sea surface temperatures measured remotely by satellite borne sensors- i.e. AVHRR data from NOAA satellites contained in the MCSST data set for the world ocean provided by the University of Miami. The images and data derived from space in this way show the strong seasonal fluctuations and interannual el Nino fluctuations of the nitrate field. the nitrate data has been used to make estimates of new production for the equatorial pacific which are compared with shipboard measurements when available. The importance of silicate as a nutrient driving new production and the ratio of nitrate to silicate has been discovered to be crucial to better understand the causes of new production variability, so we have added these parameters to our study and have begun to make estimates of these for the equatorial Pacific, derived from the weekly averaged sea surface temperatures (SSTs). The carbonate system in seawater is one of the most complex and important topics in oceanography. The system has long interested many oceanographers from various fields because it plays a major role in all three subspheres of the earth (biosphere, lithosphere, and hydrosphere). Carbon dioxide is a soluble gas that dissolves in sea water. As a result, the oceans are a potential sink for the CO2, produced by the burning of fossil fuels, and we seek to understand the role of the World Ocean in regulating atmospheric levels of CO2. With refined determinations for the various dissociation constants of carbonic and boric acids in seawater and the advances in sophisticated instrumentation for measuring the carbonate parameters, our knowledge of the CO2-carbonate system of the ocean has rapidly increased. Extensive oceanographic investigations have been carried out in the World Ocean. Those extensive studies, especially in physical oceanography, have provided an excellent foundation for other types of study, such as that of the CO2-carbonate system. This document presents the results of quasi-continuously measured CO2 concentrations in surface water and the atmosphere during 5 Pacific Marine Environmental Laboratory cruises in the Pacific and Indian Oceans. COMBATTING URBAN AIR POLLUTION THROUGH NATURAL GAS VEHICLE (NGV) ANALYSIS, TESTING, AND DEMONSTRATION
1995 12 p Presented at the CNG Conference, Cairo, Egypt, 20-21 Nov. 1994
(Contract W-31-109-eng-38)
(DE95-008300; ANL/ES/CP-85156; CONF-9411214-Summ) Avail: CASI HC A03/MF A01

Deteriorating urban air quality ranks as a top concern worldwide, since air pollution adversely affects both public health and the environment. The outlook for improving air quality in the world's megacities need not be bleak, however. The use of natural gas as a transportation fuel can measurably reduce urban pollution levels, mitigating chronic threats to health and the environment. Besides being clean burning, natural gas vehicles (NGV's) are economical to operate and maintain. The current cost of natural gas is lower than that of gasoline. Natural gas also reduces the vehicle's engine wear and noise level, extends engine life, and decreases engine maintenance. Today, about 700,000 NGV's operate worldwide, the majority of them converted from gasoline or diesel fuel. This article discusses the economic, regulatory and technological issues of concern to the NGV industry. DOE

SIMULATION OF KATABATIC FLOW AND MOUNTAIN WAVES
G. S. Poulos 1995 3 p Presented at the Mountain Meteorology, Breckenridge, CO, 17-21 Jul. 1995
(Contract W-7405-eng-36)
(DE95-010863; LA-UR-95-1280; CONF-9507120-2) Avail: CASI HC A01/MF A01

It is well-known that both mountain waves and katabatic flows frequently form in the severe relief of the Front Range of the Rocky Mountains. Occasionally these phenomena have been found to occur simultaneously. Generally, however, the large body of literature regarding them has treated each individually, seldom venturing into the regime of their potential interaction. The simulations overviewed here attempt to reproduce both atmospheric features simultaneously for two case days during the 1993 ASCOT observational program near Rocky Flats, Colorado. DOE

NO-THERMAL PLASMA PROCESSING OF VOCs AND NO(x) AT LLNL
Bernard T. Merritt, M. C. Hsiao, B. M. Penetrante, G. E. Vogtlin, and P. H. Wallman 15 Feb. 1995 23 p Presented at the Air and Waste Management Association Meeting, San Antonio, TX, 18-23 Jun. 1995
(Contract W-7405-eng-48)
(DE95-011445; UCRL-JC-120503; CONF-950646-17) Avail: CASI HC A03/MF A01

For the past few years, Lawrence Livermore National Laboratory has been conducting a comprehensive research program on the application of non-thermal plasmas for air pollution control and abatement. This program combines an extensive modeling effort with an experimental facility and test program. We believe that there are two major issues to be addressed in order to apply non-thermal plasma processing to air pollution control; these are electrical energy consumption and byproduct identification. The thrust of our work has been to understand the scalability of the non-thermal process by focusing on the energy efficiency of the non-thermal process and to identify the byproducts to ensure that effluent gases from a non-thermal processor are benign. We have compared different types of electrical discharge reactors both theoretically and experimentally. Our interests in the application of non-thermal plasmas vary from the destruction of volatile organic compounds (VOC's) to NO(x) reduction for mobile applications. This paper discusses the processing of both NO(x) and VOC's by non-thermal plasmas at LLNL. DOE

CALCULATION OF A RESIDUAL MEAN MERIDIONAL CIRCULATION FOR A ZONAL-MEAN TRACER TRANSPORT MODEL
Woo Kap Choi, Douglas A. Rotman, and Donald J. Wuebbles 1995 30 p
(Contract W-7405-eng-48)
(DE95-009474; UCRL-ID-119565) Avail: CASI HC A03/MF A01

Because of their computational advantages, zonally-averaged chemical-radiative-transport models are widely used to investigate the distribution of chemical species and their change due to the anthropogenic chemicals in the lower and middle atmosphere. In general, the Lagrangian-mean formulation would be ideal to treat transport due to the zonal mean circulation and eddies. However, the Lagrangian formulation is difficult to use in practical applications. The most widely-used formulation for treating global atmospheric dynamics in two-dimensional models is the transformed Eulerian mean (TEM) equations. The residual mean meridional circulation (RMMC) in the TEM system is used to advect tracers. In this study, the authors describe possible solution techniques for obtaining the RMMC in the LLNL two-dimensional chemical-radiative-transport model. In the first section, the formulation will be described. In sections 3 and 4, possible solution procedures will be described for a diagnostic and prognostic case, respectively. DOE

GRAVITATIONAL-RADIATION DAMPING OF COMPACT BINARY SYSTEMS TO SECOND POST-NEWTONIAN ORDER
L. Blanchet, T. Damour, B. R. Iyer, C. M. Will, and A. G. Wiseman Jan. 1995 13 p Prepared in cooperation with Observatoire de Paris, Washington Univ., and Northwestern Univ. Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-207882; IHES/P/95/4) Avail: CASI HC A03

The rate of gravitational-wave energy loss from inspiralling binary systems of compact objects of arbitrary mass is derived through second post-Newtonian (2PN) order O((Gm/r(c squared))squared) beyond the quadrupole approximation. The result has been derived by two independent calculations of the (source) multipole moments. The 2PN terms, and in particular the finite mass contribution therein (which cannot be obtained in perturbation calculations of black hole spacetimes), are shown to make a significant contribution to the accumulated phase of theoretical templates to be used in matched filtering of the data from future gravitational-wave detectors. GRAVITATIONAL WAVES FROM INSPIRALLING COMPACT BINARIES: ENERGY LOSS AND WAVEFORM TO SECOND-POST-NEWTONIAN ORDER
L. Blanchet, T. Damour, and B. R. Iyer Jan. 1995 45 p Prepared in cooperation with Raman Research Inst.
(PB95-207890; IHES/P/95/8) Avail: CASI HC A03/MF A01

Gravitational waves generated by inspiralling compact binaries are investigated to the second-post-Newtonian (2PN) approximation of general relativity. Using a recently developed 2PN-accurate wave generation formalism, we compute the gravitational waveform and associated energy loss rate from a binary system of point-masses moving on a quasi-circular orbit. The crucial new input is our computation of the 2PN-accurate 'source' quadrupole moment of the binary. Tails in both the waveform and energy loss rate at infinity are explicitly computed. Gravitational radiation reaction effects on the orbital frequency and phase of the binary are deduced from the energy loss. In the limiting case of a very small mass ratio between the two bodies, we recover the results obtained by black hole perturbation methods. We find that finite mass ratio effects are very significant as they increase the 2PN contribution to the phase by up to 52%. The results of this paper should be of use when deciphering the signals observed by the future LIGO/VIRGO network of gravitational-wave detectors. NTIS

GENERATION OF EARTHQUAKE SIGNALS
G. Kjell Feb. 1995 27 p
(PB95-211223; SP-RAPP-1994:59) Avail: CASI HC A03/MF A01

Seismic verification can be performed either as a full scale test on a shaker table or as numerical calculations. In both cases it is necessary to have an earthquake acceleration time history. The report describes generation of such time histories by filtering white noise. Analogue and digital filtering methods are compared. Different methods of predicting the response spectrum of a white noise signal filtered by a band-pass filter are discussed. Prediction of both the average response level and the statistical variation around this level are considered. Examples with both the IEEE 301 standard response spectrum and a ground spectrum suggested for Swedish nuclear power stations are included in the report. NTIS

SUPRIOIUS SEMI-DIURNAL VARIATION IN THE E.R.B.E. OUTGOING LONGWAVE RADIATION
Chandrasekhara R. Kondragunta (Maryland Univ., College Park, MD.) and Arnold Gruber (National Environmental Satellite Service, Washington, DC.) Jun. 1995 29 p
(NOAA-TR-NESDIS-84) Avail: CASI HC A03/MF A01

The Outgoing Longwave Radiation (OLR) data from the Earth Radiation Budget Experiment (ERBE) were analyzed for the period during which all three ERBE satellites were operating, i.e., December 6, 1986 to January 19, 1987, to study the diurnal variation. A cubic spline interpolation technique was used to fill the gaps between the sampled hours of OLR. The interpolated data was composited to obtain mean diurnal time series of OLR. In order to extract the diurnally varying dominant modes, an Empirical Orthogonal Function (EOF) analysis technique was applied to the normalized anomalies of the composite daily OLR. The first EOF mode explains 53.2% of the total normalized variance. Its spatial pattern is dominated by positive loadings located over the oceanic cloudy regions and its temporal variation indicates a strong semi-diurnal cycle with maxima and minima coinciding with the equator crossing times of the NOAA-9 and NOAA-10 satellites. It is argued that the semi-diurnal cycle noticed in this mode is not realistic and is caused by biases in retrieving OLR from different instruments on board NOAA-9 and NOAA-10. The temporal variation of the second EOF model indicates a true diurnal signal with most of the spatial variation occurring over the dry continental regions. In the third EOF mode, most of the variation is over cloudy regions, whose temporal variation indicates a semi-diurnal variation modulated by a large amplitude diurnal cycle. The effect of this instrumental bias is clearly evident in the global averages of the OLR. Author

ALGORITHM COMPARISON AND BENCHMARKING USING A PARALLEL SPECTRA TRANSFORM SHALLOW WATER MODEL
P. H. Worley, I. T. Foster (Argonne National Lab., IL.), and B. Toonen (Argonne National Lab., IL.) 1995 13 p Presented at the 6th Workshop on Use of Parallel Processors in Meterology, Reading, England, 24 Nov. 1994
(Contract DE-AC05-84OR-21400)
(DE95-009124; CONF-9411178-2) Avail: CASI HC A03/MF A01

In recent years, a number of computer vendors have produced supercomputers based on a massively parallel processing (MPP) architecture. These computers have been shown to be competitive in performance with conventional vector supercomputers for some applications. As spectral weather and climate models are heavy users of vector supercomputers, it is interesting to determine how these models perform on MPP's, and which MPPs are best suited to the execution of spectral models. The benchmarking of MPP's is complicated by the fact that different algorithms may be more efficient on different architectures. Hence, a comprehensive benchmarking effort must answer two related questions: which algorithm is most efficient on each computer and how do the most efficient algorithms compare on different computers. In general, these are difficult questions to answer because of the high cost associated with implementing and evaluating a range of different parallel algorithms on each MPP platform. DOE

SHEAT: A COMPUTER CODE FOR PROBABILISTIC SEISMIC HAZARD ANALYSIS, USER'S MANUAL
Katsumi Ebisawa (Japan Atomic Energy Research Inst., Tokai, Japan.), Masaaki Kondo (Japan Atomic Energy Research Inst., Tokai, Japan.), Kiyoharu Abe (Japan Atomic Energy Research Inst., Tokai, Japan.), Toshiaki Tanaka, and Michio Takani Aug. 1994 143 p In JAPANESE
(DE95-717874; JAERI-Data/Code-94-009) Avail: CASI HC A07/MF A02

The SHEAT code developed at Japan Atomic Energy Research Institute is for probabilistic seismic hazard analysis which is one of the tasks needed for seismic Probabilistic Safety Assessment (PSA) of a nuclear power plant. Seismic hazard is defined as an annual exceedance frequency of occurrence of earthquake ground motions at various levels of intensity at a given site. With the SHEAT code, seismic hazard is calculated by the following two steps. (1) Modeling of earthquake generation around a site: Future earthquake generation (locations, magnitudes and frequencies of postulated earthquakes) is modeled based on the historical earthquake records, active

fault data, and expert judgement. (2) Calculation of probabilistic seismic hazard at the site: An earthquake ground motion is calculated for each postulated earthquake using an attenuation model taking into account its standard deviation. Then the seismic hazard at the site is calculated by summing the frequencies of ground motions by all the earthquakes. This document is the user's manual of the SHEAT code. It includes: (1) outlines of the code, which include overall concept, logical process, code structure, data file used, and special characteristics of the code; (2) functions of subprograms and analytical models in them; (3) guidance of input and output data; and (4) sample run results. The code has been widely used at JAERI to analyze seismic hazard at various nuclear power plant sites in Japan. DOE

LOW-LATITUDE BOUNDARY LAYER NEAR NOON: AN OPEN FIELD LINE MODEL

L. R. Lyons, M. Schulz, D. C. Pridmore-Brown, and J. L. Roeder El Segundo, CA 15 Oct. 1994 16 p Repr. from Journal of Geophysical Research, v. 99, no. A9, Sep. 1994 p 17,367-17,377

(Grant NSF ATM-91-20072)

(ATR-93(7270)-1) Avail: CASI HC A03/MF A01

We propose that many features of the cusp and low-latitude boundary layer (LLBL) observed near noon MLT can be explained by interpreting the LLBL as being on open lines with an inner boundary at the separatrix between open and closed magnetic field lines. This interpretation places the poleward boundary of the LLBL and equatorward boundary of the cusp along the field line that bifurcates at the cusp neutral point. The interpretation accounts for the abrupt boundary and magnetosheath particles at the inner edge of the LLBL, a feature that is inconsistent with LLBL formation by diffusion onto closed field lines, and for the distribution of magnetosheath particles appearing more as one continuous region than as two distinct regions across the noon cusp/LLBL boundary. Furthermore, we can explain the existence of energetic radiation belt electrons and protons with differing pitch angle distributions within the LLBL and their abrupt cutoff at the poleward boundary of the LLBL. By modeling the LLBL and cusp region quantitatively, we can account for a hemispherical difference in the location of the equatorial boundary of the cusp that is observed to be dependent on the dipole tilt angle but not on the interplanetary magnetic field (IMF) x component. We also find important variations and hemispherical differences in that the size of the LLBL should depend strongly upon the x component of the IMF. This prediction is observationally testable. Finally, we find that when the IMF is strongly northward, the LLBL may include a narrow region adjacent to the magnetopause where field lines are detached (i.e., have both ends connected to the IMF). PERPENDICULAR ELECTRON HEATING BY ABSORPTION OF AURORAL KILOMETRIC RADIATION

D. D. Morgan, J. D. Menietti, R. M. Winglee (Washington Univ., Seattle, WA.), and H. K. Wong (Southwest Research Inst., San Antonio, TX.) Sep. 1994 31 p Revised

(Grant NAG5-2102)

(NASA-198815; NAS 1.26:198815) Avail: CASI HC A03/MF A01

We investigate the possibility of perpendicular heating of electrons and the generation of '90 deg -electron conics' by particle diffusion in velocity space due to wave-particle interaction with intense auroral kilometric radiation. This interaction is made possible by the downward shift in the R-X cutoff below the electron cyclotron frequency that occurs in the presence of warm plasma. We stimulate this condition and solve the diffusion equation using a finite difference algorithm. The results show strong perpendicular electron heating and indicate that the main characteristics of an electron conic distribution can be reproduced under these conditions. Author

LABORATORY SIMULATED HYDROTHERMAL ALTERATION OF SEDIMENTARY ORGANIC MATTER FROM GUAYMAS BASIN, GULF OF CALIFORNIA Ph.D. Thesis

Roald N. Leif 23 Jul. 1993 291 p Sponsored by Donors of the Petroleum Research Fund

(Grants NAGw-2833; NSF OCE-90-02366; NSF OCE-86-01316)

(NASA-CR-198951; NAS 1.26:198951) Copyright Avail: CASI HC A13/MF A03

High temperature alteration of sedimentary organic matter associated with marine hydrothermal systems involves complex physical and chemical processes that are not easily measured in most natural systems. Many of these processes can be evaluated indirectly by examining the geochemistry of the hydrothermal system in the laboratory. In this investigation, an experimental organic geochemical approach to studying pyrolysis of sedimentary organic matter is applied to the hydrothermal system in the Guaymas Basin, Gulf of California. A general survey of hydrothermal oils and extractable organic matter (bitumen) in hydrothermally altered sediments identified several homologous series of alkanones associated with a high temperature hydrothermal origin. The alkanones range in carbon number from C11 to C30 with no carbon number preference. Alkan-2-ones are in highest concentrations, with lower amounts of 3-, 4-, 5- (and higher) homologs. The alkanones appear to be pyrolysis products synthesized under extreme hydrothermal conditions. Hydrous pyrolysis and confinement pyrolysis experiments were performed to simulate thermally enhanced diagenetic and catagenetic changes in the immature sedimentary organic matter. The extent of alteration was measured by monitoring the n-alkanes, acyclic isoprenoids, steroid and triterpenoid biomarkers, polycyclic aromatic hydrocarbons and alkanones. The results were compared to bitumen extracts from sediments which have been naturally altered by a sill intrusion and accompanied hydrothermal fluid flow. These pyrolysis experiments duplicated many of the organic matter transformations observed in the natural system. Full hopane and sterane maturation occurred after 48 hr in experiments at 330 deg C with low water/rock mass ratios (0.29). A variety of radical and ionic reactions are responsible for the organic compound conversions which occur under extreme hydrothermal conditions. Short duration pyrolysis experiments revealed that a portion of the hydrocarbons generated from kerogen was observed to go through alkene intermediates, and the rate of alkene isomerization was influenced by the ionic strength and catalytic mineral phases. Confinement of the organic pyrolysate to the bulk sediment accelerated the rates of the biomarker epimerization reactions, suggesting that these reactions are influenced strongly by the association of the inorganic matrix, and that the relative rates of some ionic and radical reactions can be influenced by the water/rock ratio during the pyrolysis experiments. SSUSI SINGLE SENSOR AURORAL E-LAYER ALGORITHM: FUNCTIONAL DESCRIPTION

Robert E. Daniell, Jr., William G. Whartenby, and Lincoln D. Brown 6 Jul. 1994 39 p

(Contract F19628-91-C-0103)

(AD-A288630; PL-TR-94-2195) Avail: CASI HC A03/MF A01

This report describes the SSUSI single sensor Auroral E-layer algorithm developed by Computational Physics, Inc. for Phillips Laboratory and provided to the Johns Hopkins University Applied Physics Laboratory for incorporation into the operational software for SSUSI. SSUSI is an Ultraviolet Disk and Limb Imager to be flown aboard DMSP satellites for ionospheric and thermospheric remote sensing purposes. The algorithm described here uses the Lyman-alpha intensity and the intensities in two wavelength bands dominated by the Lyman-Birge-Hopfield band system from molecular nitrogen to estimate the characteristic energy and energy flux of electrons and protons in the auroral region. A simple auroral chemistry model is then used to estimate the peak density and height of the auroral E-layer. Uncertainties in the measured intensities and the algorithm parameters are estimated at each stage of the calculation and an estimate of the uncertainty in the calculated quantities is provided along with the quantities themselves. MODELING AND PARAMETERIZATION OF GRAVITY WAVE BREAKING, INTERACTIONS, AND INSTABILITY PROCESSES IN THE LOWER AND MIDDLE ATMOSPHERE Final Report, 1 Jan. 1992 - 31 Dec. 1993

David Fritts 8 Jul. 1994 5 p

(Contract F49620-92-J-0138)

(AD-A292740; AFOSR-95-0217TR) Avail: CASI HC A01/MF A01

The goal of this research were to address two sets of problems relating

to gravity wave effects in the lower and middle atmosphere. One approach was intended to apply analytic and pseudo-spectral collocation techniques for studies of wave excitation, instability, dissipation, and interaction processes thought to play important role in the circulation, structure, and variability throughout the atmosphere. A second effort was intended to apply our current understanding of the spectral character of the atmosphere motion field to the development of a parametrization scheme for the most important wave effects in large-scale models of the atmosphere.

SEISMIC STUDIES OF SUBDUCTED LITHOSPHERE Ph.D. Thesis
Mary Ann Glennon 1994 233 p
Avail: Univ. Microfilms Order No. DA9416362

This dissertation investigates dynamic processes in the mantle using source parameters, waveforms, and travel times associated with deep-focus earthquakes. First, I systematically determined the focal mechanisms and depths of all large-to-moderate sized earthquakes that occurred along the Kuril-Kamchatka in the past 30 years. My results show that the configuration of the subducting slab and the state of strain within the subducted lithosphere are,highly variable along both the strike and dip. In particular, I observed down-dip compressional strain in the northern and central portions of the arc between depths of 200 and 650 km. In these regions, deformation of the subducted slab near the base of the upper mantle is delineated by seismicity, probably in response to resistance encountered near the 670-km discontinuity. Second, I analyzed P and SH waveforms from eight deep-focus earthquakes in subduction zones of the northwestern Pacific to investigate whether complexities in broadband waveforms can be adequately explained by simple source models. Both sub-horizontal and sub-vertical ruptures are found within the same subducting system. At a depth of approximately 480 km, the length of one such rupture constrains the seismogenic thickness of the subducted slab to be approximately 40 km. Finally, using both digital and analog seismograms, I precisely measured approximately 400 arrival times of teleseismic P phases for seven earthquakes, most of which occurred since 1987 in the Kuril region, In this region, fast P azimuths residuals of deep-focus earthquakes at azimuths to the north-northeast and south-southwest are often interpreted as evidence for a deep penetrating slab. Along these azimuths, I also observed that P residuals of a deep focus earthquake in the northern Kuril-Kamchatka are significantly faster than those of both deep and shallow-focus earthquakes located beneath the Sakhalin Island near southern Kuril. My observations suggest that seismic wave speeds below depths of approximately 650 km vary along the arc. A synthesis of my results shows a correlation between the state of strain within subducted lithosphere in the upper mantle, as determined from source parameters, and the extent of slab penetration into the lower mantle, as inferred from travel-time analysis. IMPACT BEHAVIOR OF THE ACTIVE ZONE WITHIN A FROZEN SOIL PROFILE Final Report, Sep. 1990 - Aug. 1994
Niguel Picornell and Soheil Nazarian Feb. 1995 148 p
(Contract DAAL03-90-G-0196)
(AD-A292909; ARO-28201.1-GS-SAH) Avail: CASI HC A07/MF A02

The report describes a lab experiment with a pavement profile subject to a freeze/thaw cycle. The 5 x 5 x 5 ft lab specimen was instrumented with thermocouples, resistivity sensors, and 48 embedded geophones. The records of these sensors were used to delineate the progress of a freezing front through the soil profile and to implement a tomographic survey. At selected intervals, a 550-lb impulse, lasting 15 milliseconds, was imparted on a circular plate placed on the surficial asphalt layer, and the records at all geophone locations were recorded. The surface deflection bowl was used to backcalculate the moduli of all pavement layers present using a computer code: WESDEF. Then, the two sets of moduli from WESDEF and those found from the tomographic survey were used to predict the deflections at all geophone locations. The report describes the comparison of the measured with the predicted deflections to evaluate the capabilities of the backcalculation procedure in the presence of frozen and thawed soil layers. OXYGEN CHARGE STATE ABUNDANCE IN THE INNER MAGNETOSPHERE
J. F. Fennell, J. L. Roeder, M. Grande (Rutherford Appleton Lab., Chilton, England.), and B. Wilken (Max-Planck-Inst. fuer Aeronomie, Hanover, Germany.) 30 Jan. 1995 10 p
(Contract F04701-93-C-0094)
(AD-A293497; TR-95(5940)-4; SMC-TR-95-11) Avail: CASI HC A02/MF A01

The CRRES Magnetospheric Ion Composition Sensor (MICS) was used to obtain the relative oxygen charge state abundances in the earth's inner magnetosphere (3 less than L less than 7.5). These abundances were obtained for average and quiet (Kp less than or equal to 2+, absolute value of DST less than 11) conditions. They are presented as normalized spectra and compared to the predictions of Spjeldvik and Fritz (1978). These comparisons show that the observed spectra agree best with the Spjeldvik and Fritz predictions that assume an O+ source, at the high L boundary in their model, for oxygen with Q less than or equal to +3 but agree better with their predictions for a solar wind source, O(+6), for oxygen with Q greater than +3 on average. As expected, O(+) is the dominant oxygen ion at all times in the inner magnetosphere for energies greate r than 60 keV/Q. During average conditions the Q greater than or equal to +4 ions have fluxes comparable to O(+3) in the L = 4.5 - 7.5 region and are about 50% of the O(+3) fluxes in the L = 3 - 5 regions. Thus, the average O(+3) fluxes appear to represent a transition state between ionospheric and solar wind source oxygen. DTIC

MONTE CARLO CODE FOR EVALUATING THE BOUNDARY LAYER ILLUMINATION AND RADIATION BALANCE MODEL (BLIRB)
Michael B. Wells Jan. 1995 92 p
(Contract DAAL03-91-C-0034)
(AD-A293963) Avail: CASI HC A05/MF A01

The AGGIE Monte Carlo code was modified by providing an output file giving information on the location and direction of motion for each source photon and collided photon during a run. The CUBCLD1 code was developed to analyze the collision file to determine the polar and azimuthal angle distribution of the photons escaping from each side of a box-shaped cloud. The AGGIE code was modified to evaluate hemispheric emission from a box-shaped cloud. The modified code was used to provide calculational data for both a sunlight source and ground and cloud emission. The results were compared to data reported by McKee and Cox; Harshvardhan, Weinmann, and Davies; and Zardecki. The comparison shows that AGGIE is capable of providing accurate radiation transport data used for validating the BLIRB code. DTIC

VALIDATION OF THE ATMOSPHERIC TRANSMISSION LARGE-AREA ANALYSIS SYSTEM (ATLAS) Final Report
Max P. Bleiweiss Feb. 1995 44 p
(AD-A293810; ARL-TR-544) Avail: CASI HC A03/MF A01

The Atmospheric Transmission Large-Area Analysis System (ATLAS) is a unique tool that has been under development at the U.S. Army Research Laboratory since the mid-1980's. ATLAS is a nonintrusive, passive technique capable of producing two-dimensional transmittance maps of a smoke cloud in a plane perpendicular to the main-optical-axis line of sight (LOS). (Off-axis LOS's are not perpendicular but are in a fan with an angular intersect determined by the overall field of view of the imager.) The accuracy and precision of the transmission values depends on the test conditions during which the measurements are made but can be defined through the error analyses discussed in this report. The spatial resolution of the resulting transmission maps is also test specific, but, typically, is of the order of a few tens of centimeters. The temporal resolution is determined by the video rates of the imaging system, which, after preliminary low-pass filtering, yields maps at 10 Hz. ATLAS is at the stage of development that it is used on a regular basis to support smoke/obscurant field tests. For this reason, a validation process was defined and implemented in 1989. This report documents the completion of that effort as a major milestone for the laboratory during FY92. In addition, the capabilities and limitations of the ATLAS technique are discussed in detail. DEVELOPMENT OF THE MULTI-LEVEL SEISMIC RECEIVER (MLSR)
G. E. Sleefe, B. P. Engler, P. M. Drozda, R. J. Franco, and Jeff Morgan Feb. 1995 231 p
(Contract DE-AC04-94AL-85000)
(DE95-008823; SAND-94-2162) Avail: CASI HC A11/MF A03

The Advanced Geophysical Technology Department (6114) and the Telemetry Technology Development Department (2664) have, in conjunction with the Oil Recovery Technology Partnership, developed a Multi-Level Seismic Receiver (MLSR) for use in crosswell seismic surveys. The MLSR was designed and evaluated with the significant support of many industry partners in the oil exploration industry. The unit was designed to record and process superior quality seismic data operating in severe borehole environments, including high temperature (up to 200 C) and static pressure (10,000 psi). This development has utilized state-of-the-art technology in transducers, data acquisition, and real-time data communication and data processing. The mechanical design of the receiver has been carefully modeled and evaluated to insure excellent signal coupling into the receiver. DOE

A PROTOTYPE IONOSPHERIC TOMOGRAPHY SYSTEM (ITS) Final Report, 30 Jul. 1991 - 30 Apr. 1994
E. J. Fremouw and J. A. Secan 15 Jun. 1994 32 p
(Contract F19628-90-C-0116)
(AD-A293015; NWRA-CR-94-R117; PL-TR-94-2190) Avail: CASI HC A03/MF A01

Northwest Research Associates has developed a prototype ionospheric tomography system (ITS) for use with the 'Transit' satellites of the U.S. Navy Navigation Satellite System (NNSS). The NNSS satellites transmit coherent signals at 150 and 400 MHz. The ITS consists of a data-collection subsystem made up of five newly designed, largely digital ITS 105 coherent radio receivers for recording dispersive phase between the two NNSS signals, a data retrieval subsystem, and a central processor. In addition to dispersive phase, the receivers measure the signal intensities, all at 50 samples per sec (sps), for recording signal scintillation due to scattering in medium-scale (of order km) plasma-density irregularities. The dispersive phase is smoothed to one sps for use as a measure of the path-integral of plasma density (the 'total electron content,' or TEC). Data may be retrieved from on-line personal computers associated with each receiver either on diskettes or by means of modems that constitute the primary data retrieval subsystem. The data retrieval subsystem also includes one 'data collection platform' for satellite relay of data from a remote station to CONUS for subsequent modem retrieval. The central processor consists of six FORTRAN programs developed for tomographic inversion of TEC data by means of a weighted, damped, least squares formulation of discrete inverse theory. This report describes application of that theory to the central processor and briefly describes the data collection and data retrieval subsystems. DTIC

ASPECTS OF THE MAGNETOSPHERIC AMPLIFICATION PHENOMENON IN DUCTED WHISTLER-MODE WAVES Ph.D. Thesis
Thomas A. Mielke 1994 88 p
Avail: Univ. Microfilms Order No. DA9414621

Interactions between ducted whistler-mode waves and energetic particles in the magnetosphere often lead to strong wave amplification, characteristically associated with such non-linear effects as the appearance of sidebands and triggering of free-running emissions. Experiments at Siple Station, Antarctica, were conducted to study the growth process. Data from the experiment on antenna polarization effects on coupling of wave energy into the whistler-mode agree well with theory. Results of experiments aimed at determining the wave-particle interaction underlying the observed wave growth were consistent with a gyroresonance interaction but not with a Landau resonance interaction. Experiments using pulses with parabolic rather than linear frequency chirps also produced wave growth, providing the capability to test theories of the effects of spatial variations on the wave growth process. A further observed phenomenon, that of a wave power threshold below which the growth and emissions effect does not occur, was also investigated. While very suggestive, data from an experiment on the effects of artificial noise on the threshold level fail to conclusively discriminate between competing theories of wave growth (involving trapped versus non-trapped electrons interacting with the whistler-mode wave).

MIDDLE ATMOSPHERE STRUCTURE AND DYNAMICS: LIDAR STUDIES AT THE SOUTH POLE, SYOWA AND URBANA Ph.D. Thesis
Richard Laurence Collins 1994 158 p
Avail: Univ. Microfilms Order No. DA9416352

We present lidar observations of the middle atmosphere at the South Pole (90 deg S), Syowa (69 deg S, 39 deg E), and Urbana (88 deg W, 40 deg N). The South Pole stratospheric observations yield a high resolution data set of stratospheric temperature and polar stratospheric cloud (PSC) backscatter ratio profiles during the austral winter and spring of 1990. The observations show that the seasonal development of the clouds is primarily determined by the behavior of the temperature field. The PSC's are composed predominantly of nitric acid trihydrate particles. Correlation with frost-point measurements shows that nitric acid mixing ratios are depressed in the spring. The small-scale structure of the clouds appears to be controlled by gravity waves propagating upward through the clouds. Lidar measurements of the mesospheric Na layer at the South Pole in 1990 and Syowa in 1985 are used to characterize mesopause region gravity wave activity over Antarctica. The structure of the Na layer reflects the general circulation of the high-latitude mesopause. The monochromatic waves observed over Antarctica show the same general characteristics as those reported from other sites. The mean density variance of the gravity wave perturbations at the South Pole is similar to that observed at a variety of lower latitude sites. A distinct feature of the South Pole observations is the presence of strong coherent oscillations in the bottomside density contours of the Na layer close to the inertial frequency. Na Doppler/temperature lidar measurements of Na density and temperature at Urbana yield a high resolution seasonal data set of gravity wave activity. The direct measurement of the Brunt-Vaisala period allows accurate calculation of the horizontal velocity and vertical displacement from the density measurements. The

horizontal velocity and vertical displacement m-spectrum magnitudes and indices show considerable seasonal and nightly variability, behaviors which contradict the predictions of Linear Instability Theory and Scale-Dependent Diffusion Theory. We present a detailed comparison of the observations with the predictions of the Scale-Independent Diffusive Filtering Theory. The magnitudes of the m-spectrum, the form of the joint (m, omega) spectrum, the systematic relationships between the monochromatic gravity wave periods, wavelengths, and amplitudes agree remarkably well with those predicted for Scale-Independent Diffusive Filtering Theory. This observational study suggests that the complex nonlinear interactions of the gravity wave field can be modeled successfully as a diffusion process, where the diffusivity is a function of the total wave variance.

DE-1 OBSERVATIONS OF POLAR O(+) STREAM BULK PARAMETERS AND COMPARISON WITH A MODEL OF THE CENTRIFUGALLY-ACCELERATED POLAR WIND

C. Wing Ho and J. L. Horwitz 1995 14 p

(Grants NAG8-134; NAG8-822; NAG1-554; RTOP 432-20-00)

(NASA-CR-198930; NAS 1.26:198930) Avail: CASI HC A03/MF A01

A survey of bulk parameters of analyzable O(+) outward streams in the mid-altitude (3-4.7 R(sub E) geocentric distance) polar cap magnetosphere is obtained from measurements by the Retarding Ion Mass Spectrometer (RIMS) aboard the Dynamics Explorer-1 (DE-1) spacecraft. There is wide scatter in the obtained densities, but they do display discernible trends: the average O(+) density in these streams decreases from about 60 ions/cc at 3.5 R(sub E) to about 1 ion/cc at 4.6 R(sub E). The streaming velocities are somewhat more defined, and their average increases from about 8 km/s at 3.5 R(sub E) to about 12 km/s at 4.6 R(sub E). The densities and bulk velocities are inversely correlated. We have further compared these observational trends with model profiles for the centrifugally-accelerated polar wind as recently described by Horwitz et al. (1994). The large outflow velocities observed can be understood in part as centrifugally-driven by convection with ionospheric electric field magnitudes of the order 50-70 mV/m, perhaps including plasma expansion effects.

UNDERDENSE HEATING OF THE IONOSPHERE USING OBLIQUE HIGH POWER HF RADIOWAVES Ph.D. Thesis

Yuming Huang 1994 126 p

Avail: Univ. Microfilms Order No. DA9423783

This paper presents a systematic analysis of changes in ionosphere caused by underdense heating using oblique incidence high power radiowave considering the influence of earth's magnetic field. The generalized definition of the plasma field and the differential equation of electron temperature considering the earth magnetic field are presented. The field strength, electron temperature, collision frequency and the heater-induced absorption in the lower ionosphere under different heating modes (X-Mode and O-Mode) in nighttime are investigated on a self-consistent basis. The behavior of sporadic-E layers under the interaction of high power radiowaves is also reviewed and the conditions of possible F-region heating is qualitatively analyzed. Numerical calculations are carried out to investigate how the incident electric field and plasma field change the electron temperature, collision frequency and heater-induced absorption for different heating powers, frequencies and elevation angles. The data and results from a Voice of America (VOA) high power heating experiments are presented. An explanation based on primary heating and secondary heating effects is presented to explain the observed results for both a series of former Soviet Union ionospheric modification experiments and our VOA experiments. The primary heating effect is produced in the lower ionosphere, resulting in additional absorption and leading to an instantaneous decrease of amplitude of the received signal. The secondary heating effect relates to the perturbation of electron density which is quite different at different altitudes for daytime and nighttime. The analysis of these effects considers both the magnitude of the change in the steady state and the time constant for these changes.

Ellingson (Maryland Univ., College Park, MD.), and S. C. Tsay (National Aeronautics and Space Administration. Goddard Space Flight Center, Greenbelt, MD.) 1995 3 p Presented at the 4th Conference on Polar Meteorology and Oceanography, Dallas, TX, 15-20 Jan. 1995

(Contract DE-AC04-94AL-85000)

(DE95-009580; SAND-95-0571C; CONF-950153-3) Avail: CASI HC A01/MF A01

If current plans are realized, within the next few years, an extraordinary set of coordinated research efforts focusing on energy flows in the Arctic will be implemented. All are motivated by the prospect of global climate change. SHEBA (Surface Energy Budget of the Arctic Ocean), led by the National Science Foundation (NSF) and the Office of Naval Research (ONR), involves instrumenting an ice camp in the perennial Arctic ice pack, and taking data for 12-18 months. The ARM (Atmospheric Radiation Measurement) North Slope of Alaska and Adjacent Arctic Ocean (NSA/AAO) Cloud and Radiation Testbed (CART) focuses on atmospheric radiative transport, especially in the presence of clouds. The NSA/AAO CART involves instrumenting a sizeable area on the North Slope of Alaska and adjacent waters in the vicinity of Barrow, and acquiring data over a period of about 10 years. FIRE (First ISCCP (International Satellite Cloud Climatology Program) Regional Experiment) Phase 3 is a program led by the National Aeronautics and Space Administration (NASA) which focuses on Arctic clouds, and which is coordinated with SHEBA and ARM. FIRE has historically emphasized data from airborne and satellite platforms. All three program anticipate initiating Arctic data acquisition during spring, 1997. In light of his historic opportunity, the authors discuss a strawman atmospheric radiative transfer experimental plan that identifies which features of the radiative transport models they think should be tested, what experimental data are required for each type of test, the platforms and instrumentation necessary to acquire those data, and in general terms, how the experiments could be conducted. Aspects of the plan are applicable to all three programs.

FEASIBILITY OF TROPOSPHERIC WATER VAPOR PROFILING USING INFRARED HETERODYNE DIFFERENTIAL ABSORPTION LIDAR

Christian J. Grund, R. Michael Hardesty, and Barry J. Rye (Colorado Univ., Boulder, CO.) 3 Apr. 1995 61 p

(Contract DE-AI03-94ER-61761)

(DE95-009647; DOE/ER-61761/1) Avail: CASI HC A04/MF A01

Continuous, high quality profiles of water vapor, free of systematic bias, and of moderate temporal and spatial resolution, acquired over long periods at low operational and maintenance cost, are fundamental to the success of the ARM CART program. The development and verification of realistic climate model parameterizations for clouds and net radiation balance, and the correction of other CART site sensor observations for interferences due to the presence of water vapor are critically dependent on water vapor profile measurements. Application of profiles acquired with current techniques, have, to date, been limited by vertical resolution and uniqueness

of solution (e.g. high resolution infrared (IR) Fourier transform radiometry), poor spatial and temporal coverage and high operating cost (e.g. radiosondes), or diminished daytime performance, lack of eye-safety, and high maintenance cost (e.g. Raman lidar). Recent developments in infrared laser and detector technology make possible compact IR differential absorption lidar (DIAL) systems at eye-safe wavelengths. In the study reported here, we develop DIAL system performance models and examine the potential to solve some of the shortcomings of previous methods using parameterizations representative of current technologies. These models are also applied to diagnose and evaluate other strengths and weaknesses unique to the DIAL method for this application. This work is to continue in the direction of evaluating yet smaller and lower-cost laser diode-based systems for routine monitoring of the lower altitudes using photon counting detection methods. We regard the present report as interim in nature and will update and extend it as a final report at the end of the term of the contract. DOE

MULTIPARAMETER RADAR MEASUREMENTS OF PRECIPITATION IN COMPLEX TERRAIN: METEOROLOGICAL AND HYDROLOGICAL APPLICATIONS Final Technical Report
Kultegin Aydin 9 Sep. 1994 18 p
(Contract DAAL03-89-K-0158)
(AD-A290786; ARO-26982.10-GS) Avail: CASI HC A03/MF A01

The primary objective of this research program was to investigate problems related to the use of a C-band polarimetric radar for estimating the rainfall in a region with complex terrain and where storm development and structure are highly variable and poorly understood. The anticipated experimental opportunities or conclusive testing of whether dual polarization C-band reflectivity factor measurements are adequate for quantitative estimation of rainfall under these conditions did not materialize. A number of associated problems were identified and subsequently investigated. Methods for reduction of clutter and noise in rainfall fields were developed. Techniques for translating radar-derived rainfall parameters to the ground were introduced. Storm runoff simulation studies were performed based on radar measurements in rainstorms. Tomographic imaging techniques, which use microwave propagation links, were studied for rainfall measurements in complex terrain. The effects of vertical reflectivity gradients and attenuation on radar measurements in rainfall were investigated and correction algorithms were tested for the latter. Attenuation in rainfall was observed as a major problem for C-band dual-polarization reflectivity factor measurements in rain. For operational purposes there are presently no demonstrated reliable attenuation correction methods. This indicates: that S-band frequencies, which suffer little or negligible rainfall attenuation, should be the choice for operational rainfall measuring radars at this time. DTIC

AEROSOL MEASUREMENTS OVER THE PACIFIC OCEAN IN SUPPORT OF THE IR AEROSOL BACKSCATTER PROGRAM Final Technical Report, 13 Aug. 1990 - 12 Feb. 1992
Joseph M. Prospero and Dennis L. Savoie [1995] 43 p
(Grant NAG8-841)
(NASA-CR-198925; NAS 1.26:198925) Avail: CASI HC A03/MF A01

The major efforts under NASA contract NAG8-841 included: (1) final analyses of the samples collected during the first GLOBE survey flight that occurred in November 1989 and collections and analysis of aerosol samples during the second GLOBE survey flight in May and June 1990. During the first GLOBE survey flight, daily samples were collected at four stations (Midway, Rarotonga, American Samoa, and Norfolk Island) throughout the month of November 1989. Weekly samples were collected at Shemya, Alaska, and at Karamea, New Zealand. During the second GLOBE survey flight, daily samples were collected at Midway, Oahu, American Samoa, Rarotonga, and Norfolk Island; weekly samples were collected at Shemya. These samples were all analyzed for sodium (sea-salt), chloride, nitrate, sulfate, and methanesulfonate at the University of Miami and for aluminum at the University of Rhode Island (under a subcontract). (2) Samples continued to be collected on a weekly basis at all stations during the periods between and after the survey flights. These weekly samples were also analyzed at the University of Miami for the suite of water-soluble species. (3) In August 1990, the results obtained from the above studies were submitted to the appropriate personnel at NASA Marshall Space Flight Center to become part of the GLOBE data base for comparison with data from instruments used aboard the aircraft. In addition, the data will be compared with data previously obtained at these stations as part of the Sea-Air Exchange (SEAREX) Program. This comparison will provide valuable information on the representativeness of the periods in terms of the longer term aerosol climatology over the Pacific Ocean. (4) Several publications have been written using data from this grant. The data will continue to be used in the future as part of a continuing investigation of the long-term trends and interannual variations in aerosol species concentrations over the Pacific Ocean. FORECAST OF ATLANTIC SEASONAL HURRICANE ACTIVITY FOR 1994
William M. Gray 7 Jun. 1994 22 p Sponsored by NSF, and NOAA National Weather Service and Climate Analysis Center
Avail: CASI HC A03/MF A01

This paper presents details of the author's forecast for the amount of tropical cyclone activity expected to occur in the Atlantic Ocean region including the Caribbean Sea and the Gulf of Mexico during 1994. This forecast is based on the author and colleague's ongoing research relating the amount of seasonal Atlantic tropical cyclone activity to five basic physical parameters. These are: (1) the Quasi-Biennial Oscillation (QBO) of equatorial stratospheric wind; (2) the El Nino Southern Oscillation (ENSO); (3) West African Rainfall (AR) anomalies during the previous year; (4) anomalous west to east gradients of surface pressure and surface temperature (delta PT) in West Africa during February through May; and (5) Caribbean Basin Sea Level Pressure and Upper level Zonal Winds Anomalies (SLPA and ZWA respectively). Information received by the author up to 6 June 1994 indicates that the overall 1994 hurricane season should be a below average with about 5 hurricanes (average is 5.7), 9 named storms (average is 9.3) of at least tropical storm intensity, a total of about 15 hurricane days (average is 23), 35 named storm days (average is 48) and total Hurricane Destruction Potential (HDP) of 40 (average is 68). It is also expected that there should be only one intense or major hurricane of Saffir/Simpson intensity category 3, 4, or 5 this season (average is 2.2) and only about 1 major hurricane day (average is 4.5). These parameters represent an overall measure of total hurricane and tropical cyclone activity which is only about 70% of the last 44-year average. The amount of hurricane activity in this forecast has been reduced from that in the author's 19 November 1993 forecast and update discussion of 11 March 1994 at the New Orleans National Hurricane Conference. This forecast reduction is due to the slower than anticipated dissipation of the current El Nino, new estimates of West African February through May surface east-west pressure and temperature gradients, and to above average values of April-May Caribbean basin SLPA and ZWA values. This forecast will be updated on 5 August 1994, just before the beginning of the climatologically most active part of the hurricane season. The updated August forecast will make use of June and July data and should provide a more reliable forecast, particularly with regard to the African rainfall as it related to prospects for intense hurricane activity. The updated forecast will also provide a much better gage on the extent of expected dissipation of the current El Nino event. Author

SUMMARY OF 1993 ATLANTIC TROPICAL CYCLONE ACTIVITY AND VERIFICATION OF AUTHOR'S FORECAST. A YEAR OF UNANTICIPATED LIGHT HURRICANE ACTIVITY AND A POOR FORECAST: THE EXPECTED DISSIPATION OF THE EL NINO DID NOT TAKE PLACE AND CARIBBEAN BASIN SURFACE PRESSURE BECAME QUITE HIGH
William M. Gray 19 Nov. 1993 19 p Sponsored by NSF and NOAA
Avail: CASI HC A03/MF A01

This paper summarized the tropical cyclone (TC) activity which occurred in the Atlantic Basin during 1993, and verifies the author's seasonal forecast of this activity which were issued on 24 November of last year and updated

on 5 June and 4 August of this year. The 1993 hurricane season was relatively inactive with eight named storms (average 9.3) and four hurricanes (average 5.7). There was only one major (or intense) Saffir/Simpson category 3-4-5 hurricane (average is 2.2) and this storm (Emily) was only a marginal category 3 intensity for slightly less than one day. The seasonal total of hurricane days was only 10 (average is 23) and the seasonal total of named storm days was just 30 (average is 46). Only two systems (tropical cyclone Arlene in south Texas and Hurricane Emily near Cape Hatteras) affected the U.S. mainland. The author had forecast a substantially more active hurricane season. This forecast failure was primarily the result of the misjudgment of the remarkably persistent El Nino conditions which occurred this year and of the high Caribbean basin surface pressure which became established in August. The Caribbean pressure changes are believed to be unrelated to the El Nino and are a result of the intertropical covergence line being shifted southward over the South American continent. Additional unfavorable hurricane conditions included a continuing West Sahel drought. It is quite unusual for an El Nino to last through three consecutive seasons as the current El Nino event has. Actually, warm water has persisted in the equatorial Pacific through the last four hurricane seasons. The El Nino is the most dominant of the climate influences affecting Atlantic hurricane activity, tending to strongly suppress the activity. The long lasting (1991-1993) El Nino conditions had finally started weakening in June and July and this weakening was expected to continue. But, beginning in late August, a surprising resurgence of warming SST conditions occurred in the eastern Pacific. This warming led to a stronger upper tropospheric trough over the western Atlantic and Caribbean sea, and with it, enhanced vertical wind shear. All tropical cyclone activity ended after the 21st of September, a date which is normally only 60% of the way through the Atlantic cyclone season. Author

EARLY AUGUST UPDATED FORECAST OF ATLANTIC SEASONAL HURRICANE ACTIVITY FOR 1994

William M. Gray 5 Aug. 1994 24 p Sponsored by NSF and Climate Analysis Center

Avail: CASI HC A03/MF A01

This paper presents details of the author's forecast for the amount of tropical cyclone activity expected to occur in the Atlantic Ocean region including the Caribbean Sea and the Gulf of Mexico during 1994. This forecast is based on the author and colleague's ongoing research relating the amount of seasonal Atlantic tropical cyclone activity to five basic physical parameters. These are: (1) the quasi-Biennial Oscillation (QBO) of equatorial stratospheric wind; (2) the El Nino Southern Oscillation (ENSO); (3) West African Rainfall (AR) anomalies; (4) anomalous west to east gradients of surface pressure and surface temperature (delta PT) in West Africa during February through May; and (5) Caribbean Basin Sea Level Pressure and Upper Level Zonal Wind Anomalies (SLPA and ZWA respectively). Information received by the author through 4 August 1994 indicates that the overall 1994 hurricane season should be below average with about 4 hurricanes (average is 5.7), 7 named storms (average is 9.2) of at least tropical storm intensity, a total of about 12 hurricane days (average is 23), 30 named storm days (average is 46) and total Hurricane Destruction Potential (HDP) of 35 (average is 69). It is also expected that there should be only one intense or major hurricane of Saffir/Simpson intensity category 3, 4 or 5 this season (average is 2.1) and only about 1 major hurricane day (average is 4.5). These parameters represent an overall measure of total hurricane and tropical cyclone activity which is only about 55% of the last 44-year average. The amount of hurricane activity in this forecast has been reduced from that in the author's 19 November 1993 forecast and update 7 June 1994 forecast. This forecast reduction is due to the slower than anticipated dissipation of the current El Nino, new estimates of below average West African rainfall, and much above average values of June-July Caribbean basin sea level pressure. CLOUD CONDENSATION NUCLEI MEASUREMENTS IN SHIPTRAILS Annual Report, 1 Feb. 1994 - 31 Jan. 1995

James G. Hudson 13 Apr. 1995 3 p

(Contract N00014-94-1-0339)

(AD-A293302) Avail: CASI HC A01/MF A01

At the end of May the CCN spectrometer and calibration equipment were transported to Monterey for the field project. The equipment operated successfully for most of the time on 11 of the 12 research flights. For most of the time the CCN spectrometer directly monitored the ambient CCN spectrum. Occasionally, the sample aerosol was heated to obtain particle volatility. Sometimes the aerosol was size classified to obtain the relative solubility of the CCN. During some of the in-cloud passes the CCN spectrometer monitored the residue from the cloud droplets from the counterflow virtual impactor (CVI) which allows a precise determination of the CCN that are actually within the cloud droplets. QTSAW (QUICK TYPHOON SURGE AND WAVES). WAVE INFORMATION STUDIES OF US COASTLINES Final Report

Barbara A. Tracy Jan. 1995 42 p

(AD-A293172; WES-WIS-31) Avail: CASI HC A03/MF A01

This report is a user's guide for the personal-computer (PC)-based system called QTSAW (Quick Typhoon Surge and Waves). The programs and data to operate this system were developed on a 386 (33-MHz) PC and are included on two computer diskettes. The data set is the storm parameter data for all the typhoons in the Guam area (10 deg by 17 deg N latitude and 141.5 by 148.5 deg E longitude) from 1945-1991. The programs in the system create wind and pressure fields from the input storm data. These wind and pressure fields are then used as input to programs that calculate the wave and surge conditions for the Island of Guam. Several graphical display programs are available for the output results. This system was set up as part of the Wave Information Studies to help meet the needs of the Pacific Ocean Division, U.S. Army Corps of Engineers. DTIC

Timothy Liu (Jet Propulsion Lab., California Inst. of Tech., Pasadena, CA.), Roger B. Lukas (Hawaii Univ., Hilo, HI.), Pern P. Niiler (California Univ., San Diego, CA.), and Calvin T. Swift (Massachusetts Univ., Amherst, MA.) Jan. 1995 9 p

(Contract NAS5-31358)

(NASA-CR-189437; NAS 1.26:189437) Avail: CASI HC A02/MF A01

This was a Tropical Rainfall Measurement Mission (TRMM) modeling, analysis and applications research project. Our broad scientific goals addressed three of the seven TRMM Priority Science Questions, specifically: What is the monthly average rainfall over the tropical ocean areas of about 10(exp 5) sq km, and how does this rain and its variability affect the structure and circulation of the tropical oceans? What is the relationship between precipitation and changes in the boundary conditions at the Earth's surface (e.g., sea surface temperature, soil properties, vegetation)? How can improved documentation of rainfall improve understanding of the hydrological cycle in the tropics? Author

LAWS HURRICANE STUDIES Final Report, 21 Sep. 1993 - 20 Sep. 1994

John Molinari Feb. 1995 5 p

(NASA Order S-12870-F)

(NASA-CR-189438; Rept-320-6597B; NAS 1.26:189438) Avail: CASI HC A01/MF A01

The Laser Atmospheric Wind Sounder (LAWS) has recently been deselected from the Earth Observing System (EOS). A broad range of orbital altitudes and laser power are being considered for future wind lidar missions. As a result, as was anticipated in the proposed work, it may be impossible to meaningfully study tropical cyclones with lidar wind data because data coverage (i.e., swath width) is insufficient. Research on this grant has focused on how to maximize the benefits of a wind lidar regardless of the choice of platform or laser. Our studies have shown that major unsolved problems in tropical meteorology relate to the structure, dynamics, and role in tropical cyclogenesis of 'easterly waves'. These disturbances exist almost everywhere in the global subtropics. Results are described that focus upon easterly wave impacts on eastern Pacific tropical

cyclogenesis. The availability of wind lidar data would create tremendous opportunities for the study of these waves and their role in the general circulation. Author

Physically-based cloud forecasting algorithms have been developed in support of the long range goal of developing a comprehensive mesoscale numerical prediction cloud forecast system. Algorithms for forecasting cirrus clouds include development of both heterogeneous and homogeneous ice nucleation schemes, a double-moment ice crystal distribution parameterization, liquid and ice saturation calculations at very cold temperatures, and of radiative properties of cirrus. The impact of these algorithms on mesoscale prediction of cirrus has been evaluated for a number of FIRE 1 and 2 cirrus data sets. One of the FIRE stratus cases was simulated to evaluate various boundary layer cloud fractional coverage schemes. The best performing schemes have been interfaced with the RAMS radiation codes for forecasting boundary layer stratus. A convective cloud parameterization scheme designed for use in mesoscale models has been tested against data observed during the Cape over South Florida. Improvements to the cumulus parameterization scheme are now being made and tested. A new two-moment microphysics scheme has been developed, implemented and tested in RAMS. The additional degrees of freedom in this scheme allow a more realistic prediction of cloud microstructure and corresponding radar reflectivities and optical depths. DTIC

The Federal Aviation Administration (FAA) Integrated Terminal Weather System (ITWS) is supporting the development of products important for air traffic control in the terminal area. Some ITWS products will allow air traffic managers to anticipate operationally significant short-term (0-30 min) changes in ceiling and visibility (C&V) and aircraft separations necessary to avoid encounters with wake vortices. Development of such products exploits data that will by available from new FAA terminal area sensor systems. These sensor systems include Terminal Doppler Weather Radar (TDWR), Next Generation Weather Radar (NEXRAD), the Meteorological Data Collection and Reporting System (MDCRS), and the Automated Surface Observing System (ASOS). A Dynamic Atmospheric Vertical Structure Nowcast System (DAVS-NS) is being developed that will add value to ITWS by providing current analyses and short-term forecasts of the vertical atmospheric structure focused at specific sites within the terminal domain. This report summarizes the initial evaluation of the Oregon State University one-dimensional boundary layer model for its potential role within a DAVS-NS. DTIC

SUPPORT OF ENVIRONMENTAL REQUIREMENTS FOR CLOUD ANALYSIS AND ARCHIVE (SERCAA): DATABASE MANAGEMENT FACILITY Final Report, 28 Dec. 1990 - 30 Sep. 1994
Charles F. Ivaldi, Joseph Doherty, Courtney C. Scott, and Gary B. Gustafson 20 Nov. 1994 83 p
(Contract F19628-91-C-0011)
(AD-A293938; PL-TR-94-2290) Avail: CASI HC A05/MF A01

A satellite database management facility was developed to support implementation and real-data testing of new multisource, multi spectral satellite-based cloud analysis algorithms. Cloud algorithms were produced separately under Phase 1 of the Support of Environmental Requirements for Cloud Analysis and Archive (SERCAA) research and development project. The objective of the database project was to develop a unified capability to store, update, retrieve and catalog satellite and supporting data plus derived algorithm products. Data processing and storage requirements dictated a centralized database management facility capable of operating over a network of processing and mass storage systems. Based on these requirements, specifications were generated for a suitable database management facility. This was followed by development and implementation of software and hardware on the Air Force Interactive Meteorological System (AIMS) used by the Atmospheric Sciences Division at the Air Force Phillips Laboratory for SERCAA algorithm testing. Key features of the database management facility include simultaneous access to the database by multiple users, support for interactive and programmed queries, easy access to satellite and ancillary data from within application programs, network access to the database from multiple-vendor computers, and support for both on-line and removable data storage media. VALIDATION OF SPECIAL SENSOR MICROWAVE/IMAGER OCEAN SURFACE WIND RETRIEVALS IN EQUATORIAL REGIONS M.S. Thesis
Elton G. Sayward Dec. 1994 77 p
(AD-A293750) Avail: CASI HC A05/MF A01

The Fleet Numerical Meteorology and Oceanography Center (FNMOC) has the charter to provide Special Sensor Microwave/Imager (SSM/I) data to DOD and NOAA users. This tasking has led to new methods for processing SSM/I data being developed to improve NAVY SSM/I products, in particular the ability to remotely sense ocean surface winds. Currently, alternative SSM/I ocean surface wind speed algorithms include 'physical' or 'statistical' methods. Typically physical retrievals require additional data, e.g., cloud liquid water, along with SSM/I brightness temperatures while statistical methods are stand alone algorithms based on brightness temperature only. In this study four candidate wind retrieval methods proposed at the SSM/I Algorithm Symposium (June 1993) for implementation at FNMOC are examined. Limitations of the SSM/I calibration/validation data set to the midlatitude region prompted the requirement to develop a tropical data set for evaluation of alternative algorithms. Comparison of SSM/I wind retrieval methods reveal neural networks display a high wind speed bias for winds above 11 m/s and a low wind speed bias for winds below 3 m/s. The current FNMOC operational algorithm may overestimates wind speeds when water vapor is greater than 50 kg/m(exp 2). Partitioning of SSM/I retrieved wind speeds according to accuracy is by accomplished when using brightness temperature received at 37 GHz. DTIC

A NUMERICAL STUDY OF THE EFFECT OF THE GULF STREAM AND THE APPALACHIAN MOUNTAINS ON CAROLINA COASTAL FRONTOGENESIS
Liang Xu, Sethu Raman, and Rangarao V. Madala 27 Apr. 1995 21 p
(NR Proj. RR0-3303)
(AD-A293765; NRL/FR/7220-95-9774) Avail: CASI HC A03/MF A01

Three numerical experiments were conducted to understand the role of the Gulf Stream and the Appalachian Mountains on the formation of coastal frontogenesis along the mid-Atlantic coast during the winter months. A 3-dimensional, 10-layer, 1-way interactive, triple-nested hydrostatic model was used. The model physics includes dry convective adjustment, explicit large-scale precipitation, parameterized convective-scale circulations, and parameterized boundary layer physics using a similarity theory formulation. Initial conditions for the numerical model are obtained from the Second Intensive Observation Period (IOP-2) of the Genesis of Atlantic Lows Experiment (GALE). Results of the numerical experiments show that the Gulf Stream plays a significant role in developing coastal frontogenesis through transfer of large amounts of sensible and latent heats to the cold, dry atmospheric air of Arctic origin. The Gulf Stream is also found to be crucial in producing convective precipitation along the Carolina coast. On the other hand, the Appalachian Mountains, which are responsible for cold air damming, are found to play only a minor role in the coastal frontogenesis. DTIC

THE ATC OPERATIONAL EVALUATION OF THE PROTOTYPE INTEGRATED TERMINAL WEATHER SYSTEM (ITWS) AT DALLAS/FORT WORTH AND ORLANDO AIRPORTS (MAY-SEPTEMBER 1993) Final Technical Note
Thomas M. Weiss Mar. 1995 119 p
(AD-A293808; DOT/FAA/CT-TN95/1) Avail: CASI HC A06/MF A02

The Integrated Terminal Weather System (ITWS) was developed by Massachusetts Institute of Technology/Lincoln Laboratory (MITILL). The ITWS processor acquires data from Federal Aviation Administration (FAA) and National Weather Service (NWS) weather sensors in the terminal area and provides an integrated set of safety and planning weather products to air traffic personnel. An operational evaluation of the ITWS functional prototype was performed from May through September, 1993 at Dallas/Fort Worth (DFW) and Orlando (MCO) airports. ITWS geographical situation displays (6 SD) were located both at DFW and MCO as well as the Fort Worth Air Route Control Center (ARTCCXZFW) and Jacksonville ARTCC (ZJX). The purpose of testing ITWS at these sites was to evaluate various technical and operational issues of IIWS weather products and their display and usability on the GSD. DTIC

BRIGHTNESS TEMPERATURE SIMULATIONS FOR THE PHYSICAL AND SYNOPTIC INTERPRETATION OF ADVANCED MICROWAVE SOUNDING UNIT MOISTURE CHANNELS Ph.D. Thesis
Bradley Moore Muller 1993 206 p
Avail: Univ. Microfilms Order No. DA9416153

Radiative transfer simulations are performed in three phases to determine how water vapor and clouds affect passive brightness temperatures (T(sub B)s) of moisture sounding channels on the Advanced Microwave Sounding Unit (AMSU). Phase 1 employs idealized profiles of water vapor, cloud liquid water, and cloud ice as input to the radiative transfer model to investigate how AMSU frequencies at 23.8, 89, 157, 176, 180 and 182 GHz respond to clear and cloudy non-precipitating atmospheres. Phase 2 represents an effort to verify the microwave radiative transfer approach using observed data from an aircraft-mounted prototype radiometer. Phase 3 of the research employs output from a mesoscale model simulation of the ERICA IOP4 cyclone in an effort to gain insight about the synoptic interpretation of microwave water vapor image signatures. Model soundings are used in the radiative transfer code to generate synthetic 182 GHz imagery, as if a satellite were viewing the model atmosphere. In Phase 1, T(sub B)s at 23.8 GHz and 89 GHz are more strongly affected by 'altostratus' liquid clouds than by 'cirrus' clouds for equivalent water paths. Channels near 157 and 183 GHz are more strongly affected by ice clouds. Phase 2 results indicate that the radiative transfer approach is adequate for simulating observed TBS, and that TBS at the relatively high microwave frequencies considered here are very sensitive to the ice particle size distribution. Phase 3 results show that 50 percent of the radiance contribution at 182 GHs for clear atmospheres emanates from the upper 0.35 mm of precipitable water, that is, above 380-400 mb, while 90 percent comes from the top 1.5 mm. A warm radiometric feature occurs near a tropopause fold. Dry upper and middle tropospheric air over the extremely dry formerly stratospheric air brought down by the tropopause fold allow the simulated 182 GHz channel to sense the strong vertical moisture gradient below 700 mb, at the bottom edge of the upper level frontal zone. MEXICO WIND RESOURCE ASSESSMENT PROJECT
Marc N. Schwartz and Dennis L. Elliott May 1995 12 p Presented at the 25th Annual Conference and Exhibition on Wind Power, Washington, DC, 26-30 Mar. 1995
(Contract DE-AC36-83CH-10093)
(DE95-009202; NREL/TP-441-7809; CONF-950309-5) Avail: CASI HC A03/MF A01

A preliminary wind energy resource assessment of Mexico that produced wind resource maps for both utility-scale and rural applications was undertaken as part of the Mexico-U.S. Renewable Energy Cooperation Program. This activity has provided valuable information needed to facilitate the commercialization of small wind turbines and windfarms in Mexico and to lay the groundwork for subsequent wind resource activities. A surface meteorological data set of hourly data in digital form was utilized to prepare a more detailed and accurate wind resource assessment of Mexico than otherwise would have been possible. Software was developed to perform the first ever detailed analysis of the wind characteristics data for over 150 stations in Mexico. The hourly data set was augmented with information from weather balloons (upper-air data), ship wind data from coastal areas, and summarized wind data from sources in Mexico. The various data were carefully evaluated for their usefulness in preparing the wind resource assessment. The preliminary assessment has identified many areas of good-to-excellent wind resource potential and shows that the wind resource in Mexico is considerably greater than shown in previous surveys. USE OF ARM MEASUREMENTS TO IMPROVE RADIATIVE TRANSFER MODELS USED IN CLIMATE MODELS
Robert W. Bergstrom, S. Kinne, O. B. Toon, Doug Westphal, Tony Clough, and Eli Mlawer (Atmospheric and Environmental Research, Inc., Cambridge, MA.) 31 Jul. 1995 4 p Prepared in cooperation with Bay Area Environmental Research Inst., San Francisco, CA
(Contract NCC2-817)
(NASA-CR-199014; NAS 1.26:199014) Avail: CASI HC A01/MF A01

The demands of accurate predictions of radiative transfer for climate applications are well-documented. While much effort is being devoted to evaluating the accuracy of the GCM radiative transfer schemes, the problem of developing accurate, computationally efficient schemes for climate models still remains. This paper discusses our efforts in developing accurate and fast computational methods for global and regional climate models.

SPECTRAL SKY BACKGROUND IN THE IR: MEASUREMENTS WITH FTIR [SPEKTRAL HIMMELSBAKGRUND I IR-OMRADET: MAETNINGAR MED FTIR]
P. Nilsson Sep. 1994 95 p In SWAHILI
(PB95-222998; FOA-R-94-00026-3.1-SE) Avail: Issuing Activity (National Technical Information Service (NTIS))

Measurements of the sky spectral background in the region 750-2500/cm (4-13 micrometers) have been performed with an FTIR spectrometer. The measurements were made at different weather conditions and at different elevations over the horizon. In order to investigate the correlation between the sky radiance and the different weather parameters, a weather station was used at all measurements. The most apparent thing in the results is the considerable influence of the clouds on the sky radiance. Clouds generally act like greybodies but when they increase in thickness they emit like blackbodies. For a clear sky the radiance is high just over the horizon and then drops as the elevation increases towards zenith. This is because the aerosol concentration is higher at the ground and because the path through the atmosphere is longer for small elevations. The measurement results show a good agreement with results from calculations with the atmospheric program Modtran. NTIS

YELLOW SEA THERMAL STRUCTURE M.S. Thesis
Charles R. Fralick, Jr. Sep. 1994 95 p
(AD-A291159) Avail: CASI HC A05/MF A01

There exists a need in the oceanography community to be able to produce climatologies of remote or poorly sampled shallow water areas through remote sensing techniques. Our goal was to construct a three-dimensional thermal structure of the Yellow Sea based primarily upon sea surface temperature data. The ability to do this successfully could lead the way to applying these techniques elsewhere using remotely sensed SST. The shallow water and dynamic conditions of the Yellow Sea made it an ideal study area. The large MOODS observational data set for the area provided us with 15,000 observations from 1929 to 1991. For the winter months we used regression techniques on the predominantly well-mixed, vertically isothermal profiles with excellent results. For the summer we applied a feature model which extracted physically significant depths and gradients from the observations. These modeled data were statistically compared with mixed results indicating little link between SST and mixed-layer depth but good correlation between SST and thermocline gradient. We believe interannual variability and significant sampling errors in our data contributed to our mixed results. Overall, we feel our approach is robust and has potential for further applications providing data quality issues are addressed. DTIC

REMOVAL OF SCATTERED SURFACE WAVES FROM SEISMIC DATA Ph.D. Thesis
B. Blonk 16 Jan. 1995 141 p
(PB95-197802; ISBN-90-9007865-7) Avail: CASI HC A07/MF A02

Exploration seismology aims at the detection of oil- and gas-reservoirs. Therefore, detailed knowledge about the structure and rock properties of the sub-surface layers is required, especially about the deep layers. This knowledge is often obtained from seismic waves that have been reflected at the deep layers. The properties of the shallow subsurface often vary significantly. Those strong variations can give rise to complex near-surface scattered waves that depreciate the quality of land seismic data; these waves contain no information about the deep subsurface and can mask the reflections from the deep layers. In this thesis, a 3D elastodynamic inverse scattering method is presented for eliminating these near-surface scattered waves. The method is based on the estimation of a suitable shallow scattering model by a data-fitting procedure, using as much seismic data as possible. NTIS

OCEAN MASS DENSITY CALCULATIONS FROM TEMPERATURE AND SALINITY DATA
Graham D. Furnell Jun. 1994 38 p
(DSTO-TR-0023; AR-008-538) Copyright Avail: Issuing Activity

A knowledge of the mass density stratification of ocean waters is a fundamental requirement when performing calculations in the field of dynamical oceanography. Experimentally, ocean temperature and salinity stratifications can be conveniently measured. In this report, details are given of a computational procedure which uses the International Equation of State of Sea Water (IES 80) to calculate an ocean mass density stratification from temperature and salinity data. The results of calculations are presented which yield mass density stratifications at a number of locations in waters to the West and NorthWest of Australia. Author

SeaWiFS TECHNICAL REPORT SERIES. VOLUME 29: SeaWiFS CZCS-TYPE PIGMENT ALGORITHM
Stanford B. Hooker, ed., Elaine R. Firestone, ed. (General Sciences Corp., Laurel, MD.), James Aiken (Plymouth Marine Lab., England.), Gerald F. Moore (Plymouth Marine Lab., England.), Charles C. Trees (San Diego State Univ., San Diego, CA.), and Dennis K. Clark (National Oceanic and Atmospheric Administration, Camp Springs, MD.) Apr. 1995 37 p
(NASA-TM-104566; Rept-95B00096; NAS 1.15:104566) Avail: CASI HC A03/MF A01

The Sea-viewing Wide Field-of-view Sensor (SeaWiFS) mission will provide operational ocean color that will be superior to the previous Coastal Zone Color Sensor (CZCS) proof-of-concept mission. an algorithm is needed that exploits the full functionality of SeaWiFS whilst remaining compatible in concept with algorithms used for the CZCS. This document describes the theoretical rationale of radiance band-radio methods for determining chlorophyll alpha and other important biogeochemical parameters, and their implementation for the SeaWiFS mission. Pigment interrelationships are examined to explain the success of the CZCS algorithms. In the context where chlorophyll alpha absorbs only weakly at 520 nm, the success of the 520 nm to 550 nm CZCS band ratio needs to be explained. This is explained by showing that in pigment data from a range of oceanic provinces chlorophyll alpha (absorbing at less than 490 nm), carotenoids (absorbing at greater than 460 nm), and total pigment are highly correlated. Correlations within pigment groups particularly photoprotectant and photosynthetic carotenoids are less robust. The sources of variability in optical data re examined using the NIMBUS Experiment Team (NET) bio-optical data set and bio-optical model. In both the model and NET data, the majority of the variance in the optical data is attributed to variability in pigment (chlorophyll alpha, and total particulates, with less than 5% of the variability resulting from pigment assemblage. The relationships between band ratios and chlorophyll is examined analytically, and a new formulation based on a dual hyperbolic model is suggested which gives a better calibration curve than the conventional log-log linear regression fit. The new calibration curve shows that 490:555 ratio is the best single-band ratio and is the recommended CZCS-type pigment algorithm. Using both the model and NET data, a number of multiband algorithms are developed; the best of which is an algorithm based on the 443:555 and 490:555 ratios. From model data, the form of potential algorithms for other products, such as total particulates and dissolved organic matter (DOM), are suggested. Author

During last year, the Northwest Research Associates Arctic team completed the Spring SIMI field program in the Beaufort Sea. We have subsequently conducted data analysis and written papers on that data. In addition, we organized the Ice Mechanics and Arctic Modeling Workshop to be held in Anchorage, AK, April 25-28, 1995, which will report on the research findings of SIMI and will also address future research needs. During this year, we presented a paper on Sea Ice Mechanics Initiative (SIMI) at the Offshore Technology Conference in Houston, TX, in May 1994. The presentation was an attempt to foster communication between the Arctic research being done at the Office of Naval Research and the Arctic offshore-work of the oil industry. The findings of our SIMI field work are reported in our paper entitled 'Sea Ice Mechanics Research,' which appears in Volume I of the Sea Ice Mechanics and Arctic Modeling Workshop proceedings. We have written a paper entitled 'Forced-Displacement Measurements of a First-year Pressure Ridge and Keel' to be presented at Sea Ice Mechanics '95 Symposium as part of the ASME Joint Applied Mechanics and Materials summer meeting at UCLA in June 1995. The results from this data analysis show that the strength of partially consolidated ridges changes in a period of two weeks from an active component in sea ice dynamics to an inactive component, because of its strength. We participated in the preparation of a second paper for the Ice Mechanics '95 Symposium with Dr. R. S. Pritchard of IceCasting and with Drs. D. M. Farmer and Y. Xie of Institute of Ocean Sciences. This paper, entitled 'Acoustic Signatures of Falling Ice Blocks,' examines the acoustic signature from small-scale processes associated with ridging. DTIC

MULTIPLE SCATTER THEORY OF OCEAN SEDIMENTS Semiannual Report, 1 Aug. 1994 - 31 Jan. 1995
Nicholas P. Chotiros and Dennis Yelton 25 Apr. 1995 6 p
(Contract N00014-94-1-0438)
(AD-A293951; TL-AS-95-94) Avail: CASI HC A02/MF A01

To develop a new model of acoustic bottom backscatter from sandy sediments, based on a multiple scattering theory approach, and hence, properly explain observed phenomena, including Lambert's rule and frequency dependence of backscattering strength, particularly at shallow grazing angels, for which current theories are at a loss. The idea underlying our current approach to this problem is that real sediments are granular. The hypothesis we are trying to prove isthat physical mechanisms for both attenuation and scattering may be found in the interaction of acoustic waves with the granular structure. DTIC

ARABIAN SEA MIXED LAYER DYNAMICS EXPERIMENT: MOORING DEPLOYMENT CRUISE REPORT
Richard P. Trask, Bryan S. Way, William M. Ostrom, Geoffrey P. Allsup, and Robert A. Weller Jan. 1995 66 p
(Contract N00014-94-1-0161)
(AD-A293684; WHOI-95-01) Avail: CASI HC A04/MF A01

An array of surface and subsurface moorings were deployed in the Arabian Sea to provide high quality time series of local forcing and upper ocean currents, temperature, and conductivity in order to investigate the dynamics of the ocean 5 response to the monsoonal forcing characteristic of the area. The moored array was deployed during R/V Thomas Thompson cruise number 40. One Woods Hole Oceanographic Institution (WHOI) surface mooring, two Scripps Institution of Oceanography (SIO) surface moorings and two University of Washington (UW) Profiling Current Meter moorings were deployed. The moorings were deployed for a period of one year beginning in October 1994 as part of the Office of Naval Research (ONR) funded Arabian Sea experiment. Two six month deployments were planned. The moorings were deployed at 15.5N 61.5E (WHOI), 15.7N 61.30E (SIO), 15.31 61.31 (SIO), 15.7N 61.7E (UW), and 15.3N 61.7E (UW). The WHOI surface mooring was outfitted with two meteorological data collection systems. A Vector Averaging Wind Recorder (VAWR) and an IMET system made measurements of wind speed and direction, sea surface temperature, air temperature, short wave radiation, long wave radiation, barometric pressure, relative humidity and precipitation. Subsurface instrumentation included Vector Measuring Current Meters (VMCM's), Multi-Variable Moored Systems (MVMS); conductivity and temperature recorders and single point temperature recorders. Expendable bathythermograph (XBT) data and CTD data were collected while in transit to the site and between mooring locations. This report describes in a general manner the work that took place during R/V Thomas Thompson cruise number 40 which was the initial deployment cruise for this moored array. DTIC

THE TEVA EXPERIMENT CRUISE REPORT
Peter H. Dahl, Darrell R. Jackson, and Kevin L. Williams Mar. 1995 22 p Prepared in cooperation with Pennsylvania State Univ.
(Contract N00039-92-C-0100)
(AD-A293025; APL-UW-TM1-95) Avail: CASI HC A03/MF A01

A team from APL-UW made monostatic reverberation and bistatic forward scattering measurements in a shallow water channel (depth 25.6 m) located within the Dry Tortugus collection of islands (24 deg 36.7 min N 82 deg 50.7 min W) during the period 9-17 Feb. 1995. Accompanying the acoustic measurements were continuous measurements of wind speed and surface wave spectra, including wave directional information. The data will be used for sonar model development and model/data comparisons and in underwater system design, development, and performance predictions. The experiment, called the Torpedo Environmental Acoustic (TEVA) experiment, was conducted in conjunction with the Coastal Benthic Boundary Layer (CBBL) experiment organized by the Naval Research Laboratory, whose focus included measuring the geoacoustic and acoustic properties of the sea bed. The detailed environmental characterization afforded by combining assets of both the TEVA and CBBL experiments will also allow rigorous comparisons of acoustic models and measurements. DTIC

STUDIES IN MARINE TECTONICS: PROPAGATING RIFTS, DEPTH ANOMALIES AND SUBDUCTION ZONE ANISOTROPY Ph.D. Thesis
Thomas G. Shoberg 1993 125 p
Avail: Univ. Microfilms Order No. DA9415619

The tectonics of oceanic lithosphere is applied in four studies. The first two investigate how kinematic models of propagating rifts are constrained using seafloor fabric and magnetic anomaly data. The case study area is the Cobb Offset, along the Juan de Fuca ridge in the northeast Pacific Ocean basin. First I develop a method to constrain the kinematic history along this 'dueling propagator' with fabric data. Then I develop a technique that fits the rift propagation model predictions jointly to digital magnetic anomaly and seafloor fabric data. The results show that the propagation history of this region is best fit for fast rift propagation rates. The geometry is constrained most strongly by the magnetic anomaly data and the propagation rates by the fabric data. The third study constructs seafloor age relations for the Indian Ocean basin which are combined with bathymetric, sediment isopach and heat flow data to derive curves for depth and heat flow versus age. These curves are then compared with predictions from three thermal models of oceanic lithosphere evolution. They show a better fit with the GDH1 model which is characterized by a hotter, thinner lithosphere than the other models. The fourth and last study considers the observed velocity contrast between the descending lithosphere and the overlying mantle wedge in subduction zones. I quantify how much of this velocity contrast might be explained by the seismic

anisotropic behavior of constituent mineral assemblages in this region. Specifically I consider the 'remanent' anisotropy in the subducting lithosphere and the 'dynamically induced' anisotropy in the overlying mantle wedge. Three models of mantle wedge flow are considered, with parameters representative of the Japan Trench region. The results imply that seismic anisotropy can only play a strong role in explaining this velocity contrast if there is a large component of dip-axis parallel flow in the mantle above the subducting slab, but if no such flow occurs in the overlying mantle wedge, then the seismic anisotropy makes it even more difficult to explain the observed velocity contrasts. Dissert. Abstr.

THE DETERMINATION OF WAVE GROUP PARAMETERS FROM THE RESOLUTION OF INCIDENT AND REFLECTED WAVES M.S. Thesis
Gregory E. Selfridge 9 Mar. 1995 64 p
(Contract N00123-89-G-0508)
(AD-A293703) Avail: CASI HC A04/MF A01

Laboratory tests conducted to determine the effects of wave groups on rubble mound breakwater stability are analyzed. A literature review outlining the controversy regarding whether or not wave groups effect breakwater stability is given. Resolution of this controversy is proposed using two independent parameters that characterize wave groups. The two parameters are an envelope exceedance coefficient a and spectral shape gamma. The incident time series must be known to compute alpha, and an algorithm is given that will resolve incident and reflected wave time series from closely spaced wave gauges. The digital to analog simulation of laboratory waves with specified wave group characteristics is reviewed. It is recommended that further studies be conducted to parameterize the envelope exceedance coefficient alpha with a non-biased groupiness factor. DTIC

Esaias, Michael Darzi (General Sciences Corp., Laurel, MD.), Frederick S. Patt (General Sciences Corp., Laurel, MD.), Robert H. Evans (Miami Univ., FL.), and James W. Brown (Miami Univ., FL.) et al Jun. 1995 50 p Original contains color illustrations
(NASA-TM-104566-Vol-28; Rept-95B00091-Vol-28; NAS 1.15:104566-Vol-28) Avail: CASI HC A03/MF A01; 6 functional color pages

This document provides five brief reports that address several algorithm investigations sponsored by the Calibration and Validation Team (CVT) within the Sea-viewing Wide Field-of-view Sensor (SeaWiFS) Project. This volume, therefore, has been designated as the first in a series of algorithm volumes. Chapter 1 describes the initial suite of masks, used to prevent further processing of contaminated radiometric data, and flags, which are employed to mark data whose quality (due to a variety of factors) may be suspect. In addition to providing the mask and flag algorithms, this chapter also describes the initial strategy for their implementation. Chapter 2 evaluates various strategies for the detection of clouds and ice in high latitude (polar and sub-polar regions) using Coastal Zone Color Scanner (CZCS) data. Chapter 3 presents an algorithm designed for detecting and masking coccolithosphore blooms in the open ocean. Chapter 4 outlines a proposed scheme for correcting the out-of-band response when SeaWiFS is in orbit. Chapter 5 gives a detailed description of the algorithm designed to apply sensor calibration data during the processing of level-1b data. Author

SeaWiFS TECHNICAL REPORT SERIES. VOLUME 24: SeaWiFS TECHNICAL REPORT SERIES CUMULATIVE INDEX, VOLUMES 1-23
Stanford B. Hooker, ed. and Elaine R. Firestone, ed. (General Sciences Corp., Laurel, MD.) Jun. 1995 40 p
(NASA-TM-104566-Vol-24; Rept-95B00092-Vol-24; NAS 1.15:104566-Vol-24) Avail: CASI HC A03/MF A01

The Sea-viewing Wide Field-of-view Sensor (SeaWiFS) is the follow-on ocean color instrument to the Coastal Zone Color Scanner (CZCS), which ceased operations in 1986, after an eight-year mission. SeaWiFS is expected to be launched in 1995, on the SeaStar satellite, being built by Orbital Sciences Corporation (OSC). The SeaWiFS Project at the National Aeronautics and Space Administration's (NASA) Goddard Space Flight Center (GSFC), has undertaken the responsibility of documenting all aspects of this mission, which is critical to the ocean color and marine science communities. This documentation, entitled the SeaWiFS Technical Report Series, is the form of NASA Technical Memorandum Number 104566. All reports published are volumes within the series. This particular volume serves as a reference, or guidebook, to the previous 23 volumes and consists of 6 sections including: an errata, an addendum (summaries of various SeaWiFS Working Group Bio-optical Algorithm and Protocols Subgroups Workshops, and other auxiliary information), an index to key words and phrases, a list of all references cited, and lists of acronyms and symbols used. It is the editors' intention to publish a cumulative index of this type after every five volumes in the series. Each index covers the topics published in all previous editions, that is, each new index will include all of the information contained in the preceeding indices. Author

(NASA-TM-104566-Vol-13; Rept-94B00042; NAS 1.15:104566-Vol-13)
Avail: CASI HC A05/MF A01; 20 functional color pages

Although the Sea-viewing Wide Field-of-view Sensor (SeaWiFS) Calibration and Validation Program relies on the scientific community for the collection of bio-optical and atmospheric correction data as well as for algorithm development, it does have the responsibility for evaluating and comparing the algorithms and for ensuring that the algorithms are properly implemented within the SeaWiFS Data Processing System. This report consists of a series of sensitivity and algorithm (bio-optical, atmospheric correction, and quality control) studies based on Coastal Zone Color Scanner (CZCS) and historical ancillary data undertaken to assist in the development of SeaWiFS specific applications needed for the proper execution of that responsibility. The topics presented are as follows: (1) CZCS bio-optical algorithm comparison, (2) SeaWiFS ozone data analysis study, (3) SeaWiFS pressure and oxygen absorption study, (4) pixel-by-pixel pressure and ozone correction study for ocean color imagery, (5) CZCS overlapping scenes study, (6) a comparison of CZCS and in situ pigment concentrations in the Southern Ocean, (7) the generation of ancillary data climatologies, (8) CZCS sensor ringing mask comparison, and (9) sun glint flag sensitivity study. OBJECTIVE ANALYSIS OF OCEANIC DATA FOR COAST GUARD TRAJECTORY MODELS Final Report
Mar. 1994 93 p
(Contract DTRS57-93-C-00133)
(AD-A292864; USCG-D-05-95) Avail: CASI HC A05/MF A01

The Coast Guard uses ocean surface velocity fields as input to trajectory models in search planning to determine search area movement. Statistical techniques, called objective analysis, are used by meteorologists and oceanographers to combine observed data, which are irregularly distributed in space and time, to make conclusions about the total variation of the variables within a region of interest. The purpose of the Phase 1 research was to study the feasibility of adapting objective analysis techniques for use with Coast Guard data. The following research was completed. Objective analysis techniques were used to combine irregularly spaced and temporally observed ocean current velocity data in order to determine an optimally estimated velocity field and associated error field. The technique was applied to a drifting buoy data set collected by the Coast Guard. A numerical experiment was also conducted to examine the number of buoys required to determine the velocity field in a typical Search and Rescue domain.

Techniques for combining two velocity fields were also investigated. The research findings were that objective analysis techniques can be used to provide the Coast Guard with accurate estimates, in real time, of ocean surface velocity and associated error. Potential applications of this research are in support of Coast Guard Search and Rescue, Ice Patrol and Environmental Protection missions. DTIC

BIOSENSORS BASED ON CROSS-LINKING OF BIOTINYLATED GLUCOSE OXIDASE BY AVIDIN Technical Report, 1 Jan. 1994 - 25 Jan. 1995
Mark S. Vreeke and Patrick Rocca (Institut National des Sciences Appliquees de Rouen, Mont Saint Aignan, France.) 19 Jan. 1995 20 p Limited Reproducibility: More than 20% of this document may be affected by poor print
(AD-A290439; TR-014-1995) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Avidin, having four biotin binding units, cross-links and immobilizes glucose oxidase (GOX) labeled with multiple biotins (B-GOX) when solutions of B-GOX and avidin are mixed on an electrode. The H2O2 flux generated in the B-GOX catalyzed oxidation of glucose by dissolved O2 is measured as an electroreduction current at a horseradish peroxidase (HRP) redox conducting hydrogel electrode poised at +100 mV (Ag/AgCl). The sensitivity of the resulting glucose sensor is 0.14A/sq cm/M with a linear range up to 2mM glucose. DTIC

EFFECTS OF AIR BUBBLES ON RABBIT BLOOD BRAIN BARRIER
G. Bolstad, A. Hjelde, and A. O. Brubakk 1993 4 p
(PB95-195293) Avail: Issuing Activity (National Technical Information Service (NTIS))

In the present investigation three groups of six animals were infused with an isoosmotic solution of NaCl w/Macrodex and 1 percent Tween. The solution was saturated with air bubbles. Infusion of degassed NaCl solution alone affected white, but not grey matter of both hemispheres. This indicates that the infusion of NaCl, as such, at least partly may explain the formation of edema, in white matter, while this does not seem to be the case in grey matter. It is thus suggested that factors connected to infusion procedures may affect the Blood Brain Barrier (BBB) of rabbits. NTIS

ARTERIAL GAS BUBBLES AFTER DECOMPRESSION IN PIGS WITH PATENT FORAMEN OVALE
A. Vik, B. M. Jenssen, and A. O. Brubakk 1993 13 p Prepared in cooperation with Trondheim Univ., Norway
(PB95-195319) Avail: Issuing Activity (National Technical Information Service (NTIS))

With patent foramen ovale (PFO), thought to be a risk factor for some forms of decompression sickness (DCS), venous bubbles may pass through the patent opening to become arterial bubbles. We exposed 14 anesthetized, spontaneously breathing pigs to air at 5 bar (500 kPa, absolute pressure) for 30 min and then rapidly decompressed at 2 bar/min to 1 bar. We measured intravascular pressures, blood gases, and with transesophageal echocardiology, bubbles in the pulmonary artery and ascending aorta. Autopsy showed that six of the pigs had a PFO. Arterial bubbles occurred more frequently in the PFO group (in six out of six) than in the non-PFO group (in two out of eight, P less than 0.01). When arterial bubbles were detected, the venous bubble count and the pulmonary artery pressure tended to be lower in pigs with PFO than in pigs without a PFO. We conclude that a PFO increases the risk of arterial bubbles after decompression. NTIS

EFFECT OF OXYGEN AND DECOMPRESSION BUBBLES ON INERT GAS WASHOUT
V. Flook, A. O. Brubakk, O. Eftedal, I. M. Holmen, and A. L. Ustad 13 Sep. 1994 109 p
(PB95-196556; STF23-A94031) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report describes experiments designed to answer two questions: How does the use of increased oxygen in the breathing gas affect inert gas washout and How does the presence of decompression bubbles affect the washout of inert gas. The experiments were carried out on pigs, were designed in such a way that the influence of oxygen was studied separately from the influence of decompression bubbles, and involved direct measurement of blood nitrogen concentrations. The conclusions are: Increased partial pressure of oxygen slows down the rate of nitrogen washout to a degree which relates to the level of inspired oxygen; The presence of decompression bubbles slows the removal of inert gas from the body and this slowing relates to the number of mixed venous nitrogen concentration; The pressure of large numbers of decompression bubbles causes further uptake of nitrogen following return to normobaric conditions. This report provides information on the research supported in Fiscal Year 1994 by the Medical Applications and Biophysical Research Division of the Office of Health and Environmental Research. A brief statement of the scope of the following areas is presented: dosimetry; measurement science; radiological and chemical physics; structural biology; human genome; and medical applications. Summaries of the research projects in these categories are presented. DOE

IMPLEMENTATION AND PERFORMANCE OF THE PSEUDOKNOT PROBLEM IN SISAL
J. Feo and M. Ivory Dec. 1994 15 p Presented at the High Performance Functional Computing, Denver, CO, 9-11 Apr. 1995
(Contract W-7405-eng-48)
(DE95-009573; UCRL-JC-119529; CONF-9504126-1) Avail: CASI HC A03/MF A01

The Pseudoknot Problem is an application from molecular biology that computes all possible three-dimensional structures of one section of a nucleic acid molecule. The problem spans two important application domains: it includes a deterministic, backtracking search algorithm and floating-point intensive computations. Recently, the application has been used to compare and to contrast functional languages. In this paper, we describe a sequential and parallel implementation of the problem in Sisal. We present a method for writing recursive, floating-point intensive applications in Sisal that preserves performance and parallelism. We discuss compiler optimizations,

runtime execution, and performance on several multiprocessor systems. DOE

DECOMPRESSION ILLNESS, OBSERVABLE BUBBLES. (SESSION K)
O. Eftedal, S. Koteng, and A. O. Brubakk 1993 4 p Prepared in cooperation with Trondheim Univ., Norway
(PB95-195285) Avail: Issuing Activity (National Technical Information Service (NTIS))

A long period of training is required for Doppler raters to reach a standard where they can work independently grading Doppler recordings for intravascular gas bubbles. The aim of this study was to evaluate Transesophageal Echocardiography (TEE) imaging and a grading system with 6 levels as a method for quantifying bubbles. A video tape with 20 1-minute TEE recordings was shown individually to 20 persons. None of the raters had any previous experience with bubble grading. A total of 400 gradings were performed. 293 gradings were consistent with what had been protocolled, 100 differed by 1 grade, 6 differed by 2 grades and 1 differed by 3 grades. We conclude that TEE imaging is well suited for quantitative evaluation of intravascular gas bubbles, even by persons with little previous experience. The grading scale used in the experiments can probably be improved by altering the definitions of grade 1 and 2. NTIS

DETECTING INTRAVASCULAR GAS BUBBLES IN ULTRASONIC IMAGES
O. Eftedal and A. O. Brubakk Nov. 1993 9 p Prepared in cooperation with Trondheim Univ., Norway
(PB95-195301) Copyright Avail: Issuing Activity (National Technical Information Service (NTIS))

To study the effects of decompression on the human body, a reliable system for determining the presence and number of intravascular gas bubbles is required. Detection methods involving ultrasound enable portable, non-invasive systems that can be used in many different situations to be developed. A system capable of identifying single bubbles, even when the number of bubbles is high, would give a linear measure of the total number of intravascular gas bubbles. In scanned two-dimensional ultrasonic images, the grey scale value of each pixel is obtained through a logarithmic amplification of the amplitude of the reflected ultrasound from the corresponding sample volume. Gas bubbles appear as bright 'blobs' in the images. By digitizing the images, simple computer programs for automatic identification of such blobs are feasible. Systems for digitizing and transferring ultrasonic images to computers are commercially available. We present a computer program, EchoBubble, that performs automatic identification and quantification of intravascular gas bubbles in digitized images. NTIS

CONTROL OF SKIN BLOOD FLOW IN THE NEUTRAL ZONE OF HUMAN BODY TEMPERATURE REGULATION Final Report
Margaret V. Savage, George L. Brengelmann, Donald E. Roberts, and Robert S. Pozos 4 Nov. 1994 37 p
(AD-A291499; NHRC-94-27) Avail: CASI HC A03/MF A01

In humans, matching of heat loss and heat production in the 'neutral' zone, defined operationally in terms of a range of skin temperatures (Tsk), is accomplished by regulation of skin blood flow (SkBF). In four men and four women, we investigated the control of SkBF in this range by setting Tsk at 33 and 35 C in a square wave pattern (15 min at each temperature) or a step pattern (60 min at 33 C separating short periods at 35 C) by means of water sprayed over the entire body except the head, neck, and one forearm. Forearm blood flow (FBF) followed the pattern of Tsk, both in the forearm in which Tsk followed that of the rest of the body and in the arm exposed to room air (average local Tsk 31.22 C). Esophageal temperature (Tes) rose after Tsk fell and vice versa. This inverse relationship is predicted by a simple one-compartment thermal model in which control of SkBF is simulated as a linear combination of skin and core temperature (Tc). Similar patterns of Tsk applied to only one arm had little influence on FBF. We conclude that the feedforward reflex influence of Tsk on SkBF overcompensates for the effect of Tsk on thermal balance in the neutral zone so that equilibrium Tc has an inverse relationship to Tsk. ELECTROMYOSTIMULATION, CIRCUITS AND MONITORING
Donald F. Doerr [1994] 5 p
(NASA-TM-110741; NAS 1.15:110741) Avail: CASI HC A01/MF A01

One method to determine the benefit of electromyostimulation (EMS) requires an accurate strength assessment of the muscle of interest using a muscle force testing device. Several commercial devices are available. After a pre-EMS muscle assessment, a protocol with accurately controlled stimulation parameters must be applied and monitored. both the actual current and the resultant muscle force must be measured throughout the study. At the conclusion of the study, a reassessment of the muscle strength must be gathered. In our laboratory, electromyostimulation is being studied as a possible countermeasure to the muscle atrophy (degeneration) experienced in space. This muscle loss not only weakens the astronaut, but adversely affects his/her readaptation to 1-g upon return from space. Muscle atrophy is expected to have a more significant effect in long term space flight as anticipated in our space station. Our studies have concentrated on stimulating the four major muscle groups in the leg. These muscles were stimulated sequentially to allow individual muscle force quantification above the knee and ankle. The leg must be restrained in an instrumented brace to allow this measurement and preclude muscle cramping. Derived from text

CONFERENCE PERSPECTIVE. NEUROIMMUNOMODULATION: STRESS AND IMMUNE FUNCTION
Michael C. Powanda (M/P Biomedical Consultants, Mill Valley, CA.) and Matthew J. Kluger 9 Feb. 1995 11 p Conference held in Albuquerque, NM, 7-9 Oct. 1994
(Contract N00014-95-1-0124)
(AD-A291351) Avail: CASI HC A03/MF A01

The bidirectional communication and interaction between the brain and the immune system is one of the most exciting areas of biomedical research. Although many symposia contain sessions relating to the above topic (e.g. Experimental Biology 1994, Neurosciences), there are few meeting devoted exclusively to this topic. Most of these have been in foreign countries, which limits the participation of American scientists. Some 25 distinguished scientists lectured in the workshop/symposium, and another 50-60 scientists were participants. The symposium was held in a state-of-the-art conference facility, and there was ample opportunities for one-on-one discussion of science. A more detailed description of the symposium is provided. MEMBRANE TRANSPORT: A CELLULAR PROBE OF HEAT STROKE Midterm Report
John S. Willis 2 Feb. 1995 37 p
(Contract DAMD17-93-J-3031)
(AD-A293327; Rept-10-21-RR194-207) Avail: CASI HC A03/MF A01

Red blood cells of guinea pig were used to explore the effects of

temperatures above 37 C on membrane permeability to Na+ and K+ as part of an effort to evaluate the Energy Depletion Hypothesis of heat stroke. Cell Na+ and K+ does not change at 41 C and 45 C for up to 2 hours of incubation in simple saline medium. Na-K pump activity measured as ouabain-sensitive K+ influx increases with warming, as do Na+ influx and K influx. The rise in the pump activity matches the rise in Na+ influx quantitatively, accounting for the lack of change in Na+ cell. The rise in Na+ influx is in the face of a decrease in activity of Na-H exchange transport capacity. The rise in K+ influx consists largely of activation of a single, carrier-mediated path, K-C1 cotransport and corresponds to an apparent activation of this path in the reverse direction (K+ efflux), leading to dumping of K+ at elevated temperature. Na-K-C1, a third passive carrier pathway, shows a temperature optimum between 30 C and 37 C. A new hypothesis proposes that these diverse responses to temperature change contribute to the maintenance of ion balance. DTIC

ELECTROMAGNETIC FIELD EXPOSURE DOSIMETER Final Report, Sep. 1992 - May 1993
A. C. Feaga, M. P. Hilliard, and R. Link 28 Jul. 1994 32 p
(AD-A293191; NSWCDD/TR-94/76) Avail: CASI HC A03/MF A01

The growing concern about adverse health effects caused by electromagnetic radiation prompted the ideas for this dosimeter. Data have been presented that link prolonged exposure to electromagnetic radiation from power lines to leukemia and some types of cancer. At present, though, there is a lack of recording instrumentation to measure the prolonged exposure of an individual; thus, it is not possible to correlate properly the amount of exposure or dose to health effects. With the recent advances in small, low-power devices, a small measuring device can be developed. Once this is built, a large data base can be obtained to help correlate electromagnetic field exposure to health conditions. The objective of this project is to develop an instrument which can measure electromagnetic fields over a prolonged period of time. The instrument would be small, say about the size of a radio Walkman, and would be worn throughout the day while taking data, as the individual goes about normal activities. A PC would be used to retrieve the data from the instrument at the end of the day. The dosimeter comprises a triaxial ferrite-loaded coil sensor, a set of amplifiers and filters, analog-to-digital converters, a microcontroller, and random access data memory. The signals from the sensor are filtered into three frequency ranges: one to measure 60-Hz exposure and two harmonics, another to measure high-energy pulsed energy, and a third frequency range to record the activity level of the individual. The signals from the filters are digitized and read into a microcontroller. The microcontroller performs a few calculations and controls the flow of the data to either random access memory or to a computer. A computer is used to retrieve the data from the dosimeter, and can store and display the measured data. DTIC

EVALUATION OF CALIBRATION PARAMETERS AND PERFORMANCE OF THE VIDEO IMAGING TECHNIQUE OF ASSESSING EXPOSURE (VITAE SYSTEM) M.S. Thesis
Keith M. Groth Aug. 1994 128 p
(AD-A289023; AFIT/CI/CIA-94-130) Avail: CASI HC A07/MF A02

Assessing exposures to chemicals that can be absorbed through the skin presents the industrial hygienist with a perplexing and sometimes frustrating dilemma. The fact that three of the articles appearing in the February 1993 AIHA Journal addressed surface wipe sampling is a testament to an increasing concern over the impact of dermally absorbed chemicals. In addition to increased awareness of percutaneous absorption as a potentially major factor in total body burden, this concern probably is fueled by frequent reductions in the allowable levels of many airborne contaminants for the workplace. As allowable workplace levels drop, the percentage of total body burden that is a result of dermal absorption may increase. This is especially true if dermal exposures are not controlled as rigorously as inhalation exposures. In fact, in many instances where the chemical has a low vapor pressure and is not aerosolized, dermal absorption is the primary route of exposure. DTIC

FORWARD RAPID ROTATION SHIFTWORK IN USAF AIR TRAFFIC CONTROLLERS: SLEEP, ACTIVITY, FATIGUE AND MOOD ANALYSES Interim Technical Report, 10 Aug. - 3 Sep. 1992
Thomas D. Luna, Jonathan French, Jennifer L. Mitcha, and Kelly J. Neville 9 Dec. 1994 33 p
(AF Proj. 7930)
(AD-A293448; AL/CF-TR-1994-0156) Avail: CASI HC A03/MF A01

The purpose of this study was to evaluate the shift-specific sleep, general activity levels, mood and cognitive performance of air traffic controllers (ATC's) working a forward 2-2-2 rapid rotation shift schedule. ATC's recorded their sleep, oral temperature and subjective fatigue levels, took a computerized cognitive performance battery (N=13) and completed the Profile of Mood States questionnaire (POMS) (N=12). Actigraphs were used to objectively monitor general activity levels and score sleep and the restlessness of scored sleep (N=9). Analyses were made on the basis of duty shift, post-shift, day of shift, and duty location. There was significantly more actigraph scored sleep, subjectively reported sleep and subjectively measured fatigue and confusion for the ATC's while they were on duty on the night-shift. The night-shift was also associated with decreased vigor and general activity levels. Significantly more sleep was reported following the first day on each of the three shifts than following the second. Significantly more sleep was reported and scored by actigraph following the swing-shift than following the day-shift. A comparison group of non ATC day-workers reported more post-shift sleep than the ATC's. The radar approach ATC's reported greater confusion and less vigor than the tower ATC's. Insufficient trials were available for direct performance analysis. DTIC

USE OF BODY SURFACE HEAT PATTERNS FOR PREDICTING AND EVALUATING ACUTE LOWER EXTREMITY PAIN AMONG SOLDIERS Final Report, 15 Dec. 1989 - 30 Sep. 1994
Richard A. Sherman 12 Dec. 1994 53 p
(Contract MIPR-90MM052D)
(AD-A292829) Avail: CASI HC A04/MF A01

This project determined (1) that neither thermographs or podoscopes can be used to predict which basic trainees are likely to develop significant lower limb pain during training, (2) that thermography is not clinically useful in tracking changes in training related lower limb pain, (3) that contact thermographs are not useful in the TMC environment due to their inaccuracy, that videothermographs are too cumbersome and expensive to use relative to the information provided in the TMC environment, but that infrared beam thermometers are valuable adjuncts to assessment and tracking, (4) that having trainees wear shock absorbing inserts throughout basic training does not reduce the incidence and severity of lower limb pain, and (5) that training related stress fractures probably do heal faster when exposed to pulsing electromagnetic fields. SIMULATION OF OCULOMOTOR POST-INHIBITORY REBOUND BURST FIRING USING A HODGKIN-HUXLEY MODEL OF A NEURON
John D. Enderle and Edward J. Engelken 13 Feb. 1995 7 p
(AF Proj. 7755)
(AD-A293821; AL/AO-PC-1995-0012) Avail: CASI HC A02/MF A01

A number of theories have been reported on post saccade phenomenon describing dynamic overshoot, glissadic overshoot and undershoot, and undershoot, all naturally and frequency occurring saccadic eye movements. Electrophysiological evidence for post-inhibitory rebound burst firing activity during saccadic eye movements is prevalent in the literature. However, the cause for the phenomenon is not known. Marked inhibition of neurons within the Paramedian Pontine Reticular Formation often results in post-inhibitory rebound burst firing activity at the beginning and end of a saccade. In this paper, post-inhibitory rebound burst firing activity after marked hyperpolarization is postulated to occur in the Paramedian Pontine Reticular Formation due to a low membrane threshold voltage. With this biophysical property, a single neuron is capable of firing at high rates automatically and without stimulation when released from inhibition.

Simulations using the Hodgkin-Huxley model of a neuron demonstrate that a single neuron is capable of firing at high. rates automatically without stimulation when released from inhibition. DTIC

LASER INDUCED VITREORETINAL SCARRING. EVALUATION OF CAUSATIVE FACTORS AND A THERAPEUTIC APPROACH Final Report, 1 Sep. 1991 - 30 Sep. 1994
Nava Naveh and Naphthali Savion 10 Mar. 1995 50 p
(Contract DAMD17-91-Z-1031)
(AD-A293742) Avail: CASI HC A03/MF A01

Eyes subjected to laser exposure develop an inflammatory reaction, leading to scarring and bleeding, ensuing in visual impairment. This study demonstrated two main findings. (1) The angiogenic (neovascularization) activity of vitreous from lasered eye in rats cornea: The DPI an NADPH inhibitor curtailed significantly angiogenesis, as well as the initial vascular response. (2) Vitreous of lasered eyes enhances cell proliferation of retinal pigment epithelium, vascular endothel: This unique finding explains the development of visual impairment weeks and months post laser of subjects unaware of being hit by laser. Therefore subjects exposed to laser should be screened regularly to find laser lesions and a therapeutic regimen of antioxidants and/or steroidal should be initiated. DTIC

DYNAMICAL ANALYSIS OF THE CORIOLIS EFFECT WHICH CAUSES SPACE DISORIENTATION
Takao Suzuki, Jiro Koo (Tokai Univ., Hiratsuka, Japan.), and Masaki Kume (Mukaino-oka Technical High School, Japan.) Oct. 1994 10 p In JAPANESE
(ISSN 0389-4010)
(NAL-TR-1258) Avail: CASI HC A02/MF A01

The coriolis effect or illusion is a sensation of angular motion in response to an inclination of the head when the head is undergoing a passive rotation. A dummy head including three gyros and three accelerometers was assembled, and was supported with a pivot and four springs to simulate human neck mechanisms. The dummy head was tilted on a rotating table and the data obtained by the inertial sensors were analyzed to explain the cause of the Coriolis effect responsible for the illusion. In conclusion, the force acting on the dummy head is proportional to the angular velocity of the rotating table as well as to the linear velocity of the tilting motion. The force is found to be well described mainly by the principle of the coriolis acceleration. Author

USING COMPUTERIZED NEUROPSYCHOLOGICAL TESTING TO ASSESS AVIATOR SKILLS Final Technical Report
Christopher F. Flynn and Raymond B. King Dec. 1994 21 p
(AF Proj. 7755; AF Proj. ILIR)
(AD-A293227; AL/AO-TR-1994-0174) Avail: CASI HC A03/MF A01

Successful pilots must be cognitively and psychologically 'fit' to preserve cockpit situational awareness while executing complex job demands in an unforgiving environment. The neuropsychological attributes of successful U.S. Air Force (USAF) aircrew, however, are largely unstudied. To conveniently collect a large sample of aviators data for comparison to mission performance, an easy-to-use and reliable test delivery system is required. The Neuropsychiatrically Enhanced Flight Screening (N-EFS) program is one product of an effort by Armstrong Laboratory's (AL) Neuropsychiatry Branch (AOCN). N-EFS measures the cognitive functioning (using the Multidimensional Aptitude Battery, MAB; and CogScreen) and psychological attributes and crew resource management potential (using the Personal Characteristics Inventory PCI; and the Revised NEO-Personality Inventory, NEO-PI-R) of all USAF pilot candidates. This data will establish a range of cognitive attributes of pilot applicants, and will provide MAB CogScreen baseline data for future reference. The N-EFS program also seeks to validate the MAB, CogScreen, NEO-PI-R. and PCI as future tools for pilot selection and understanding situational awareness. N-EFS builds on earlier AL/AOCN efforts to develop a 'field-friendly,' self-administered, computerized psychometric testing battery to define attributes of successful pilots. DTIC

LUMINANCE EFFECTS ON VISUAL ACUITY AND SMALL LETTER CONTRAST SENSITIVITY Final Report
Jeff Rabin Feb. 1995 15 p
(AD-A293310; USAARL-95-14) Avail: CASI HC A03/MF A01

The purpose of this study was to evaluate the effects of luminance on visual acuity (VA) and small letter contrast sensitivity (SLCS). Computer-generated letter charts were used to measure VA and SLCS (6/7.5 (20/25) Snellen equivalent) as a function of stimulus luminance. Letter size (VA) and contrast (SLCS) were varied in equal logarithmic steps, making the task and scoring procedure comparable for the two types of measurement. Both VA and SLCS decreased with decreasing luminance, but the effect was far greater in the contrast domain. Reducing luminance from 116 cd/rn2 to 0.23 cd/sq m produced a 3 x reduction in VA, but a 17 x reduction in SLCS. The greater sensitivity of SLCS to luminance endured even after correction for greater measurement variability. SLCS is a sensitive approach for detecting resolution loss undisclosed by standard measures of VA. It may be useful for monitoring visual loss from light attenuation in early cataracts, and for detecting subtle resolution loss from neural or pathologic factors in ocular and neuroophthalmologic disease. PSYCHOLOGICAL PILOT SELECTION IN THE US AIR FORCE, THE LUFTWAFFE, AND THE GERMAN AEROSPACE RESEARCH ESTABLISHMENT Final Technical Report
Monika Gnan, Christopher F. Flynn, and Raymond E. King Feb. 1995 33 p
(AD-A293779; AL/AO-TR-1995-0003) Avail: CASI HC A03/MF A01

As financial resources for the U.S. Air Force (USAF) and the German Luftwaffe (LW) dwindle, reducing attrition from military aviation training becomes vital. Finding the optimal mixture of applicant personality, stamina, and psychomotor skills for aviation is a goal as complicated as it is elusive. This paper compares the USAF, LW and German Aerospace Research Establishment (DLR) pilot selection programs. The LW and DLR utilize a sequential psychological selection system including apparatus tests, psychological interviews and behavioral observations, while in the USAF psychological selection does not play an important role. Instead, medical standards, flight screening, and training attrition are used as USAF selection criteria. However, a new USAF program, Neuropsychiatrically Enhanced Flight Screening (N-EFS) will examine the personality characteristics of pilot applicants for further study. The USAF and LW could learn from the strengths and weaknesses of their respective selection programs. The opportunity for cooperative research is even greater, considering that the USAF and LW pilot students share common jet pilot training. DTIC

VISUAL TRACKING OF SELF-OCCLUDING ARTICULATED OBJECTS
James R. Rehg and Takeo Kanade 31 Dec. 1994 42 p Presented at the International Conference on Computer Vision, Boston, MA, Jun. 1995

Sponsored in part by NASA George Marshall Space Flight Center
(Grant NGT-50559)
(AD-A292894; CMU-CS-94-224) Avail: CASI HC A03/MF A01

Computer sensing of hand and limb motion is an important problem for applications in human-computer interaction, virtual reality, and athletic performance measurement. We describe a framework for local tracking of self-occluding motion, in which parts of the mechanism obstruct each others visibility to the camera. Our approach uses a kinematic model to predict occlusion and windowed templates to track partially occluded objects. We analyze our model of self-occlusion, discuss the implementation of our algorithm, and give experimental results for 3D hand tracking under significant amounts of self-occlusion. These results extend the DigitEyes system for articulated tracking described in 22, 21 to handle self-occluding motions. DTIC

VISUAL PROCESSING OF OBJECT VELOCITY AND ACCELERATION Final Technical Report, 15 Jan. 1992 - 14 Jan. 1995
Suzanne McKee 6 Mar. 1995 17 p
(Contract F49620-92-J-0156)
(AD-A292789; AFOSR-95-0243TR) Avail: CASI HC A03/MF A01

The main objective of this project was the analysis of the detection of trajectory signals in random motion noise. Results from experiments demonstrated that detection was limited by the probability of mismatch, not noise density per se; detection was based on a motion signal, not a form or position signal; detection was limited by higher-order aspects of motion processing, not the ratio of signal to noise in the primary motion detectors. The Yuille-Grzywacz 'Motion Coherence' model was modified to provide a computational model for these findings. Computer simulations showed that this model was adequate to reproduce our results. In addition, three other projects were supported by this grant: motion transparency from speed signals alone; speed discrimination for targets moving in depth; trajectory motion detection in three-dimensional noise. Nine papers from this project have been accepted in referred journals; one additional paper has been submitted. Four chapters were also supported by this grant. DTIC

CONTEXTUAL INTERFERENCE EFFECTS ON ACQUISITION AND TRANSFER OF A COMPLEX MOTOR TASK Interim Report, Oct. 1993 - Mar. 1994
Barry P. Goettl Feb. 1995 15 p
(Contract F41622-92-D-0006)
(AD-A293788; AL/HR-TP-1994-0034) Avail: CASI HC A03/MF A01

Research in motor skill and verbal memory suggests that random sequencing of trials results in retention and transfer that is superior to blocked presentation of trials. The contextual interference effect is based largely on relatively simple motor and verbal tasks. The present study explores the generalizability of the contextual interference effect to a complex flight simulator task. Subjects were assigned to three groups: whole-task training, low contextual interference, and high contextual interference. Results indicated that whole task subjects showed the best retention and that the two contextual interference groups did not differ. Additionally, all three groups showed equivalent performance on the transfer task. These results suggest that the contextual interference effect may not generalize to complex tasks. DTIC

FORCE AND VISION RESOLVABILITY FOR ASSIMILATING DISPARATE SENSORY FEEDBACK
Bradley J. Nelson and Pradeep K. Khosla Feb. 1995 48 p
(Contract DAAL03-91-G-0272)
(AD-A293581; CMU-RI-TR-95-11) Avail: CASI HC A03/MF A01

Force and vision sensors provide complementary information, yet they are fundamentally different sensing modalities. This implies that traditional sensor integration techniques that require common data representations are not appropriate for combining the feedback from these two disparate sensor. In this paper, we introduce the concept of vision and force sensor resolvability as a means of comparing the ability of the two sensing modes to provide useful information during robotic manipulation tasks. By monitoring the resolvability of the two sensing modes with respect to the task, the information provided by the disparate sensors can be seamlessly assimilated during task execution. A nonlinear force/vision serving algorithm that uses force and vision resolvability to switch between sensing modes is proposed. The advantages of the assimilation technique is demonstrated during contact transitions between a stiff manipulator and rigid environment, a system configuration that easily becomes unstable when force control alone is used. Experimental results show that robust contact transitions are made by the proposed nonlinear controller while simultaneously satisfying the conflicting task requirements of fast approach velocities, maintaining stability, minimizing impact forces, and suppressing bounce between contact surfaces. SPECIFIC METHOD FOR TASK-BASED INTERACTION DESIGN
E. Hollnagel, P. Hougaard, R. Rosness, T. Paulsen, and O. Oegard 1994 20 p Prepared in cooperation with Computer Resources International A/S, Denmark), and ESA. ESTEC, Noordwijk, Netherlands
(PB95-196440; STF75-S93007) Avail: Issuing Activity (National Technical Information Service (NTIS))

The developments in computers and information technology have led to a growing dependence on the proper functioning of human-machine interaction (HMI). It is therefore important that the design of HMI is addressed as a specific problem and that proper concepts and methods are developed. The design process serves to increase the constraints governing the situation so that only one option or alternative is left for each requirement. HMI design must therefore be supported by methods that can elicit the requirements, determine the constraints and options, and finally assist in achieving the proper combination of requirements and options that constitutes the desired solution. The paper describes such a method, based on a systematic task analysis. The design is developed based on a definition of the functional requirements which then are combined with information about presentation styles and standards and dialog design principles. The Task Based Interaction Design method is illustrated by an example from a space application. NTIS

RELEASEABLE UNCONSTRAINED INFLATABLE BODY PROTECTOR Patent
Frederick C. Guill, inventor (to Navy) 6 Nov. 1994 8 p Filed 11 Aug. 1993
(AD-D017350; US-Patent-5,362,098; US-Patent-Appl-SN-104682; US-Patent-Class-280) Avail: US Patent and Trademark Office

A device for providing crash protection to people aboard a land, air, sea or space vehicle is described. A crash sensor mounted on the vehicle is used to sense a crash, impact or jarring motion. Data from the crash sensor is then transmitted via wireless communication by a signal transmitter to a signal receiver mounted on a harness worn by a crew member or passenger. When a crash signal is received, inflation mechanisms inflate inflatable bladders mounted on the harness, thereby protection the person wearing the harness. DTIC

ERECT, NEUTRAL AND SLUMP SITTING POSTURES: A STUDY OF THE TORSO LINKAGE SYSTEM FROM SHOULDER TO HIP JOINT Final Report, Dec. 1983 - Dec. 1985
Herbert M. Reynolds Oct. 1994 175 p
(Contract F33615-84-C-0507)
(AD-A293239; AL/CF-TR-1994-0151) Avail: CASI HC A08/MF A02

Sitting postures representative of a maximum erect, neutral and maximum slumped spinal curvature were defined by comparable anatomical pointmarks in three dimensional space. Nine, male, unembalmed cadavers were measured with a roentgen stereophotogrammetric system. The results describe thoracic and lumbar curvatures in three postures and the locations of specific landmarks representing the shoulder joint, spinal column, and hip joint in a three dimensional seat reference system. In addition to the three dimensional analysis of sitting posture, the range of notion for each motion segment measured in the spine was calculated. These data were used to evaluate the contribution of specific lumbar motion segments in the change of sitting posture from maximum erect to maximum slump. To evaluate the condition of each subject's musculoskeletal system, osteological, morphological and physiological procedures were used to describe the sample. DTIC

DEVELOPMENT AND COMPUTER IMPLEMENTATION OF DESIGN/ANALYSIS TECHNIQUES FOR MULTILAYERED COMPOSITE STRUCTURES. PROBABILISTIC FIBER COMPOSITE MICROMECHANICS M.S. Thesis, Mar. 1987 Final Report, 1 Sep. 1984 - 1 Oct. 1990
Thomas A. Stock 19 Jun. 1995 193 p
(Grant NAG3-550)
(NASA-CR-198979; NAS 1.26:198979) Avail: CASI HC A09/MF A03

Probabilistic composite micromechanics methods are developed that simulate expected uncertainties in unidirectional fiber composite properties. These methods are in the form of computational procedures using Monte Carlo simulation. The variables in which uncertainties are accounted for include constituent and void volume ratios, constituent elastic properties and strengths, and fiber misalignment. A graphite/epoxy unidirectional composite (ply) is studied to demonstrate fiber composite material property variations induced by random changes expected at the material micro level. Regression results are presented to show the relative correlation between predictor and response variables in the study. These computational procedures make possible a formal description of anticipated random processes at the intraply level, and the related effects of these on composite properties. Author

HUMAN FACTORS AT THE FAA TECHNICAL CENTER: BIBLIOGRAPHY Technical Note, Dec. 1993 - Dec. 1994
Earl S. Stein, ed., Edward Buckley, ed., and Kathy Mann, ed. (Princeton Economic Research, Inc., NJ.) Dec. 1994 47 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(AD-A288638; DOT/FAA/CT-TN94/50) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Since the Federal Aviation Administration (FAA) arrived in Atlantic City in 1958, there have been ongoing efforts in aviation human factors. These efforts have taken many forms and have focused on both the ground and air sides of the airspace system. Psychologists, engineers, systems analysts, computer scientists, and others have participated in the studies that have led to the numerous reports and papers cited in this bibliography. While the listing is probably not all inclusive, it covers virtually all work that is referenced in automated data bases plus publications that were identified by current and past researchers, but which never made it to the computerized listings. This bibliography is meant to highlight the work that has gone on over the years. While many of the documents cited are still available from the Technical Center library, or from the authors themselves, the editors do not suggest that everything is retrievable, and, in fact, much of the older work has been superseded by more modern technology and thinking. The research of 30 years ago has served as a foundation for the human factors engineering that that is being done today. The references are provided in alphabetical order and indexed by numbers associated with subject matter categories. Human factors research is alive and continues to progress in the FAA and at the Technical Center. Author

HUMAN-COMPUTER INTERACTION (HCI) SPECIALIZATION TRACK MASTERS OF SOFTWARE ENGINEERING (MSE) PROGRAM
Carol L. Hoover 1 Mar. 1995 13 p
(AD-A292895; CMU-CS-95-123) Avail: CASI HC A03/MF A01

There is an increasing demand for software to implement human-computer interfaces. Software engineers who develop these interfaces need an understanding of the interactions between the human, the available computer technology, and human tasks. They should also

understand empirical methods used to evaluate the usability of existing human-computer interfaces. The Human-Computer Interaction Specialization Track, which is an option within the Masters of Software Engineering (MSE) Program at Carnegie Mellon University, enables graduate software engineering students to obtain knowledge and skills related to the design, implementation, and evaluation of interactive computing systems. Students can acquire hands-on experience in the design of computer technology to support individual users as well as group interactions. The track is flexible in that it allows students to choose their own set of track courses from a list of approved HCI courses. This report describes the track rationale and requirements and presents educational guidelines to help students select courses. The report includes a list of approved courses and brief course synopses. The report is based on the author's work in developing specialization tracks for the MSE program. The author started this work during the spring of 1993. DTIC

VERTICAL IMPACT TESTING OF TWO HELMET-MOUNTED NIGHT VISION SYSTEMS Interim Report, Jun. 1993 - Dec. 1993
Chris E. Perry Jun. 1994 25 p
(AD-A293055; AL/CF-SR-1994-0013) Avail: CASI HC A03/MF A01

The Air Force is investigating the use of helmet-mounted technology to improve pilot performance. One potential draw-back to the new helmet systems is the potential for increased neck injuries during emergency ejection due to the helmet's weight and center-of-gravity. A recent test program evaluated the risk of neck injury of two helmet-mounted night vision systems by subjecting an instrumented manikin (ADAM) to +Gz impacts using a vertical deceleration tower. The helmets were the Concept 6 from Night Vision Corporation and the ANVIS 49/49 from ITT. Results indicate that both helmets were lighter than previous helmets, and met the Interim Head and Neck Criteria. They also produced neck loads in an ACES 2 seat that are less than what a standard helmet produces in a B-52 seat, and produced neck loads in a B-52 seat that are less than the maximum (400 lbs) required for major neck injury (fracture, etc.). FOUNDATIONS OF TECHNOLOGY FOR CONSTRUCTING HIGHLY RELIABLE DISTRIBUTED REALTIME SYSTEMS Final Report, 1 Aug. 1991 - 30 Sep. 1994
David C. Luckham 30 Sep. 1994 12 p
(Grant AF-AFOSR-0354-91)
(AD-A293254; AFOSR-95-0235TR) Avail: CASI HC A03/MF A01

We have investigated event-based specification and constraint language extensions of our Rapide prototyping language. We have also investigated testing methods and tools for detecting constraint violations in simulations of distributed time-sensitive avionics systems and control systems. Rapide models the behavior of a distributed system by generating causal event simulations. A causal event simulation is a timed poset (partially ordered set of events with timing). Dependencies between events as well as their timing are captured in the poset execution model, thus providing a more detailed and precise picture of the behavior of a realtime, distributed system than current simulation technology based upon sequential traces of events. Posets allow more powerful constraint specifications than traces, e.g., asynchronous behavior. This work has developed (1) basic algorithms for implementing poset computations, (2) a constraint language for specifying behavior in terms of posets, and (3) automatable algorithms and tool-set for detecting constraint violations in posets. To establish the feasibility of scaling this simulation technology to practical avionics examples, we have applied the technology to developing high level systems architectures of avionics systems. We have also applied constraint monitoring of the avionics simulations to detect design errors. The avionics systems studied include the IBM ADAGE helicopter avionics system architecture, and a high level architecture of the Boeing DARTS system for building flight simulators. DTIC

HIGH SPEED RANDOM ACCESS, FOURIER TRANSFORM HOLOGRAPHIC ASSOCIATIVE AND HIGH DENSITY TWO-PHOTON THREE-DIMENSIONAL OPTICAL MEMORIES BASED ON BACTERIORHODOPSIN Final Report
Robert R. Birge Jan. 1995 36 p
(Contract F30602-91-C-0084)
(AD-A293389; RL-TR-95-6) Avail: CASI HC A03/MF A01

The goals were to optimize bacteriorhodopsin based photochromic and photorefractive materials for use in optical memories. Two spatial light modulators (SLM's) based on bacteriorhodopsin were developed, one that could be controlled via applied voltage and the other controlled by light. The former performed below target specification; whereas the latter achieved diffraction efficiencies two-fold above target. Preliminary results on the three-dimensional data cube were sufficiently exciting to adjust the first year statement of work to also include the optimization of the bacteriorhodopsin data cube. DTIC

IMPLEMENTATION OF KIVA-3 ON DISTRIBUTED MEMORY MIMD COMPUTERS
O. Yasar, T. Zacharia, R. Aggarwal, A. A. Amsden, and J. R. Baumgardner 1995 7 p Presented at the High Performance Computing 1995, Tucson, AZ, 9-13 Apr. 1995
(Contract DE-AC05-84OR-21400)
(DE95-010288; CONF-950431-2) Avail: CASI HC A02/MF A01

KIVA-3 is the latest version of a 3-D Finite Difference CFD code developed by Amsden for combustion engine simulations. A distributed-memory implementation has many advantages for problems that hardly fit affordable existing memory banks. Previous attempts to parallelize

KIVA-2 by Yasar, et al. were focused mostly on diffusion solvers because of their heavy time consumption during execution. The study suggested a complete parallelization of the code, including advection and spray dynamics, along with the use of a block-wise decomposition scheme to assure an efficient load balancing and a low communication/computation ratio. Here, the authors report rather a general analysis of the issues involved in such a distributed implementation for the latest version of the code, KIVA-3, on MIMD parallel systems. A more detailed analysis of the code and corresponding algorithms have already been implemented by Yasar and will be published soon. DOE

AN ASSESSMENT OF WORLDWIDE SUPERCOMPUTER USAGE
H. J. Wasserman, M. L. Simmons, and A. H. Hayes Jan. 1995 121 p
(Contract W-7405-eng-36)
(DE95-009879; LA-UR-95-375) Avail: CASI HC A06/MF A02

This report provides a comparative study of advanced supercomputing usage in Japan and the United States as of Spring 1994. It is based on the findings of a group of US scientists whose careers have centered on programming, evaluating, and designing high-performance supercomputers for over ten years. The report is a follow-on to an assessment of supercomputing technology in Europe and Japan that was published in 1993. Whereas the previous study focused on supercomputer manufacturing capabilities, the primary focus of the current work was to compare where and how supercomputers are used. Research for this report was conducted through both literature studies and field research in Japan. DOE

CLASS OF SERVICE IN THE HIGH PERFORMANCE STORAGE SYSTEM
S. Louis and D. Teaff (IBM Federal Systems Div., Houston, TX.) 10 Jan. 1995 14 p Presented at the International Federation of Information Processing International Conference on Open Distributedd Processing, Brisbane, Australia, 21-24 Feb. 1995
(Contract W-7405-eng-48)
(DE95-007959; UCRL-JC-119754; CONF-950286-1) Avail: CASI HC A03/MF A01

Quality of service capabilities are commonly deployed in archival mass storage systems as one or more client-specified parameters to influence physical location of data in multilevel device hierarchies for performance or cost reasons. The capabilities of new high-performance storage architectures and the needs of data-intensive applications require better quality of service models for modern storage systems. HPSS, a new distributed, high-performance, scalable, storage system, uses a Class of Service (COS) structure to influence system behavior. The authors summarize the design objectives and functionality of HPSS and describes how COS defines a set of performance, media, and residency attributes assigned to storage objects managed by HPSS servers. COS definitions are used to provide appropriate behavior and service levels as requested (or demanded) by storage system clients. They compare the HPSS COS approach with other quality of service concepts and discuss alignment possibilities. DOE

THE LINUX OPERATING SYSTEM: AN INTRODUCTION
Shahid H. Bokhari Jun. 1995 21 p Sponsored by University of Engineering and Technology, Lahore, Pakistan
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-198178; NAS 1.26:198178; ICASE-95-49) Avail: CASI HC A03/MF A01

Linux is a Unix-like operating system for Intel 386/486/Pentium based IBM-PCs and compatibles. The kernel of this operating system was written from scratch by Linus Torvalds and, although copyrighted by the author, may be freely distributed. A world-wide group has collaborated in developing Linux on the Internet. Linux can run the powerful set of compilers and programming tools of the Free Software Foundation, and XFree86, a port of the X Window System from MIT. Most capabilities associated with high performance workstations, such as networking, shared file systems, electronic mail, TeX, LaTeX, etc. are freely available for Linux. It can thus transform cheap IBM-PC compatible machines into Unix workstations with considerable capabilities. The author explains how Linux may be obtained, installed and networked. He also describes some interesting applications for Linux that are freely available. The enormous consumer market for IBM-PC compatible machines continually drives down prices of CPU chips, memory, hard disks, CDROMs, etc. Linux can convert such machines into powerful workstations that can be used for teaching, research and software development. For professionals who use Unix based workstations at work, Linux permits virtually identical working environments on their personal home machines. For cost conscious educational institutions Linux can create world-class computing environments from cheap, easily maintained, PC clones. Finally, for university students, it provides an essentially cost-free path away from DOS into the world of Unix and X Windows. Author

A MICROECONOMIC SCHEDULER FOR PARALLEL COMPUTERS Final Report
Ion Stoica, Hussein Abdel-Wahab, and Alex Pothen May 1995 21 p Presented at the Workshop on Job Scheduling Strategies for Parallel Processing
(Contracts NAS1-19480; RTOP 505-90-52-01; DE-FG05-94ER-25216; NSF CCR-90-24954)
(NASA-CR-198153; NAS 1.26:198153; ICASE-95-33) Avail: CASI HC A03/MF A01

We describe a scheduler based on the microeconomic paradigm for scheduling on-line a set of parallel jobs in a multiprocessor system. In addition to the classical objectives of increasing the system throughput and reducing the response time, we consider fairness in allocating system resources among the users, and providing the user with control over the relative performances of his jobs. We associate with every user a savings account in which he receives money at a constant rate. When a user wants to run a job, he creates an expense account for that job to which he transfers money from his savings account. The job uses the funds in its expense account to obtain the system resources it needs for execution. The share of the system resources allocated to the user is directly related to the rate at which the user receives money; the rate at which the user transfers money into a job expense account controls the job's performance. We prove that starvation is not possible in our model. Simulation results show that our scheduler improves both system and user performances in comparison with two different variable partitioning policies. It is also shown to be effective in guaranteeing fairness and providing control over the performance of jobs. Author

A PHENOMENOLOGICAL FINITE ELEMENT MODEL OF PART BUILDING IN THE STEREOLITHOGRAPHY PROCESS
R. S. Chambers, T. R. Guess, and T. D. Hinnerichs 1995 10 p Presented at the 6th International Conference on Rapid Prototyping, Dayton, OH, 4-8 Jun. 1995
(Contract DE-AC04-94AL-85000)
(DE95-008437; SAND-94-2565C; CONF-9506149-2) Avail: CASI HC A02/MF A01

The finite element method has been used to develop the framework for a tool that can be used to model the structural deformation arising from the stereolithography build process. Such a tool when fully developed can facilitate numerical studies aimed at evaluating build parameters and

build styles. Although the current software makes no attempt to capture all the physics of the process, provisions for three important build features have been made: (1) laser path history including scanning rate and depth of cure, (2) structural linkage, and (3) time varying material behavior. For demonstration purposes, a three dimensional finite element code was modified to include a phenomenological material model of solidification. The model was based on cure shrinkage and stress relaxation data collected from in-situ tests on individual strands drawn using 3D Systems' stereolithography apparatus (SLA-250). To depict the directed path of solidification within layers, a finite element birthing scheme was conceived to activate elements along the predetermined coordinate path of the laser. Structural linkage was enforced by joining element strands of layers when laser paths connect or overlap, respectively. A limited number of analyses have been performed to contrast simple build styles. DOE

USER'S MANUAL FOR THE SCANNING FAST FIELD PROGRAM (SCAFFIP) EOSAEL VERSION 1.0
John M. Noble and Dave Marlin Jan. 1995 115 p
(AD-A291445; ARL-TR-282) Avail: CASI HC A06/MF A02

The Scanning Fast Field Program (SCAFFIP) is an atmospheric acoustic propagation model incorporating many of the effects on the environment on the sound field such as geometrical spreading, refraction, diffraction, molecular absorption, and complex ground impedance. SCAFFIP provides range estimations from the sensor or target for signal-noise of -10, -5, 0, 5, and 10 dB (re: 20 micro-Pa) with azimuth for a given geometry, sound level of target at a given frequency, and meteorological profile. The meteorological profile and the geometry provides the model the ability to calculate the sound speed profile. The geometry profile is required because the angular dependence of the sound speed on the wind direction is relative to the direction of propagation. This model works over a flat-earth and a nonturbulent atmosphere. Even with these restrictions, the model performs very well for many scenarios. The model contains a friendly user interface requiring a minimum amount of information to run the model. There are also flags that can be set to obtain more detailed information. DTIC

AN EXECUTABLE SPECIFICATION FOR THE MESSAGE PROCESSOR IN A SIMPLE COMBINING NETWORK Final Report
David Middleton Jun. 1995 39 p
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-198174; ICASE-95-47; NAS 1.26:198174) Avail: CASI HC A03/MF A01

While the primary function of the network in a parallel computer is to communicate data between processors, it is often useful if the network can also perform rudimentary calculations. That is, some simple processing ability in the network itself, particularly for performing parallel prefix computations, can reduce both the volume of data being communicated and the computational load on the processors proper. Unfortunately, typical implementations of such networks require a large fraction of the hardware budget, and so combining networks are viewed as being impractical. The FFP Machine has such a combining network, and various characteristics of the machine allow a good deal of simplification in the network design. Despite being simple in construction however, the network relies on many subtle details to work correctly. This paper describes an executable model of the network which will serve several purposes. It provides a complete and detailed description of the network which can substantiate its ability to support necessary functions. It provides an environment in which algorithms to be run on the network can be designed and debugged more easily than they would on physical hardware. Finally, it provides the foundation for exploring the design of the message receiving facility which connects the network to the individual processors. Author

SENSOR FUSION AND NONLINEAR PREDICTION FOR ANOMALOUS EVENT DETECTION
Jose V. Hernandez, Kurt R. Moore, and Richard C. Elphic Mar. 1995 15 p Presented at the SPIE International Symposium on Aerospace/Defense Sensing and Dual-use Photonics, Orlando, FL, 17-21 Apr. 1995
(Contract W-7405-eng-36)
(DE95-009429; LA-UR-95-883; CONF-950472-4) Avail: CASI HC A03/MF A01

The authors consider the problem of using the information from various time series, each one characterizing a different physical quantity, to predict

the future state of the system and, based on that information, to detect and classify anomalous events. They stress the application of principal components analysis (PCA) to analyze and combine data from different sensors. They construct both linear and nonlinear predictors. In particular, for linear prediction the authors use the least-mean-square (LMS) algorithm and for nonlinear prediction they use both backpropagation (BP) networks and fuzzy predictors (FP). As an application, they consider the prediction of gamma counts from past values of electron and gamma counts recorded by the instruments of a high altitude satellite. DOE

We study both the complexity and approximability of various graph and combinatorial problems specified using two dimensional narrow periodic specifications. The following two general kinds of results are presented. (1) We prove that a number of natural graph and combinatorial problems are NEXPTIME- or EXPSPACE-complete when instances are so specified. (2) In contrast, we prove that the optimization versions of several of these NEXPTIME-, EXPSPACE-complete problems have polynomial time approximation algorithms with constant performance guarantees. Moreover, some of these problems even have polynomial time approximation schemes. We also sketch how our NEXPTIME-hardness results can be used to prove analogous NEXPTIME-hardness results for problems specified using other kinds of succinct specification languages. Our results provide the first natural problems for which there is a proven exponential (and possibly doubly exponential) gap between the complexities of finding exact and approximate solutions. DOE

(PB95-196317; STF31-A94033) Avail: Issuing Activity (National Technical Information Service (NTIS))

The FAMOS Flexfeed project has been established to focus feeding of small parts in assembly systems. The project aims at finding more flexible feeder solutions for small parts. Modularity, standard units and cost effective use of sensors are keywords for more flexible feeders that will be included in a new 'tool-box concept'. In addition to new feeding methods and solutions, the project partners expect knowledge gained in the area of feeding technology as an important result from the project. Intermediate results in the project will be applied and tested in the end-user facilities during the project. Practical use of new technology or new use of old technology are keywords for success. DEVELOPMENT OF BERMUDA: A RADIATION TRANSPORT CODE SYSTEM. PART 3: A ONE-DIMENSIONAL ADJOINT NEUTRON TRANSPORT CODE
Tomoo Suzuki (Nuclear Energy Data Center, Japan.), Akira Hasegawa, Shun-ichi Tanaka, and Hiroshi Nakashima Jul. 1994 29 p
(DE95-717875; JAERI-Data/Code-94-002-Pt-3) Avail: CASI HC A03/MF A01

A radiation transport code system BERMUDA has been developed for one-, two-, and three-dimensional geometry. The purpose of the development is to establish a basis of an accurate shielding calculation method for general use. The time-independent transport equation is numerically solved using a direct spatial integration method in a multigroup model, to obtain spatial, angular, and energy distribution of neutron, gamma rays, or adjoint neutron flux. Reported is the deveiopment of an adjoint neutron transport code for one-dimensional spherical geometry. Adjoint neutron flux is used in a sensitivity analysis or in a perturbation calculation. Use of the spherical harmonics expansion is avoided in representing anisotropy of both angular flux and scattering cross section. A group-angle transfer matrix is obtained by integrating double-differential cross sections numerically, taking energy-angle correlation into account. A first collision source method is utilized for a case of point source. Angular flux distribution is obtained by integrating the transport equation over a line segment along each angular discrete ordinate toward each spatial mesh point. A fine energy grid method is used, with a rebalancing scheme concerning the number of gain and loss of particles over each spatial region and also in each energy grid. Validity of the present code BERMUDA-1DNA has been tested for five sample problems by comparing the calculated results with those from the forward neutron transport code BERMUDA-1DN. The tests have shown that accurate results are obtainable with BERMUDA-1DNA. The derivation of the adjoint equation, the calculational method, and the validity tests are described. Job control languages, input data specifications, and output data are also described so that the present report is available as a user's manual. DOE

THE ROLE OF ADVANCED ENGINEERING SIMULATION IN MODEL-BASED DESIGN
P. J. Hommert and J. H. Biffle 1995 6 p Presented at the Agile Manufacturing Conference, Albuquerque, NM, 16-17 Mar. 1995
(Contract DE-AC04-94AL-85000)

(DE95-008815; SAND-95-0492C; CONF-9503112-2) Avail: CASI HC A02/MF A01

The agile manufacturing paradigm engenders many new concepts and work approaches for manufacturing operations. A technology often invoked in the concept of agility is modeling and simulation. Few would disagree that modeling and simulation holds the potential to substantially reduce the product development cycle and lead to improve product reliability and performance. Advanced engineering simulation can impact manufacturing in three areas: process design, product design, and process control. However, despite that promise, the routine utilization of modeling and simulation by industry within the design process is very limited. Advanced simulation is still used primarily in a troubleshooting mode examining design or process problems after the fact. Sandia National Laboratories has been engaged in the development of advanced engineering simulation tools for many years and more recently has begun to focus on the application of such models to manufacturing processes important for the defense industry. These efforts involve considerable interaction and cooperative research with US industry. Based upon this experience, this presentation examines the elements that are necessary for advanced engineering simulation to become an integral part of the design process. DOE

A GRAPHICAL PROGRAMMING LANGUAGE FOR SERVICE ROBOTS IN SEMI-STRUCTURED ENVIRONMENTS Ph.D. Thesis

David Spencer Lees 1994 154 p

Avail: Univ. Microfilms Order No. DA9422101

One of the main obstacles to programming a robot to do useful work is the difficulty of establishing effective, efficient communication between the programmer and the robot. In many environments we cannot depend on CAD drawings or a pre-existing assembly sequence to specify the motions that the robot must execute. However, in most cases the programmer can envision the task that the robot is to accomplish. The difficulty lies in creating a user interface that effectively communicate the programmer's wishes to the robot. To address this problem, an environment for programming robot manipulations with graphical symbols (RoboGlyph) was developed, and experiments were conducted to evaluate its performance. Programs are assembled by dragging symbols representing robot positions and actions onto a 'story-board' that stores the sequence of motions needed to perform a task. Also, force-sensing is used to detect and control interactions with the environment, so the user is not responsible for fine-positioning tasks. The RoboGlyph system is being used to program a service robot for severely disabled (high-level quadriplegic) users. In service applications, it is valuable if the users of a robot can modify its manipulation programs themselves. RoboGlyph was designed to be easier to use and more reliable than traditional text-based programming languages and to be accessible to a wider user population. Experiments with RoboGlyph have shown that, after only one or two hours of training, computer literate health care professionals with no robotics experience can write working robot programs as quickly as expert robot programmers. Expert programmers who use RoboGlyph can program at least as fast as they can with textual robot programming languages, after only one hour of training. The programs written by all RoboGlyph users were much easier to read and maintain than those written in text-based languages. Dissert. Abstr.

RASSP BENCHMARK 1 EXECUTABLE REQUIREMENTS USER'S MANUAL Project Report

Allan H. Anderson and Gary A. Shaw 20 Dec. 1994 48 p

(Contract F19628-95-C-0002)

(AD-A290060; RASSP-2; ESC-TR-94-114) Avail: CASI HC A03/MF A01

This User's Manual describes the installation and use of a set of computer programs and data files which comprise the Executable Requirement for the first benchmark in the RASSP program. The VHDL programs provide a simulation of a Synthetic Aperture Radar processor and a test bench for the simulation. Several C-language utility programs and an image display program are provided. Two sets of data, one from an airborne radar and one synthetic, and images created from the data by a C-language implementation of the SAR algorithm are described. Example scripts for execution of the simulation on Vantage and Mentor simulators are presented along with performance data from example runs. DTIC

FISHFINDE: INTERACTIVE SOFTWARE PACKAGE TO PREDICT FISH LOCATIONS USING SATELLITE IMAGE DATA AND FISH SPECIES BEHAVIOR RULES Final Report

Robert A. Arnone, R. A. Oriol, R. Crout, and Paul M. Martinolich 10 Feb. 1995 31 p

(AF Proj. R03-5-B)

(AD-A293394; NRL/MR/7420-94-7566) Avail: CASI HC A03/MF A01

A software program has been developed to aid in the prediction of fish location. Satellite and geophysical oceanographic databases have been assembled for the west coast of the U.S. which are used to predict the locations of fish. A user interactive graphical interface written in Interactive Data Language visually displays the databases and connects a series of fish rules by performing logical operations. The resultant bitmap displays the intersection of the rules which are the locations of possible fish locations. The fish rules are still under development. The software provides a real time interactive display for testing and developing an understanding of fish behavior. DTIC

UNIFICATION OF LARCH AND Z-BASED OBJECT MODELS TO SUPPORT ALGEBRAICALLY-BASED DESIGN REFINEMENT: THE LARCH PERSPECTIVE M.S. Thesis

Catherine J. Lin Dec. 1994 165 p

(AD-A289235; AFIT/GSC/ENG/94D-15) Avail: CASI HC A08/MF A02

This research describes the feasibility of developing object-oriented LARCH specifications, part of a dual approach for formally extending object-oriented analysis models using LARCH and Z. The first phase consisted of two steps: establishing a set of transformation heuristics for algebraically representing object models and implementing a robust LARCH parser. The LARCH parser produced abstract syntax trees (AST's) of objects forming the basis for analyzing the similarities and differences between Z-based and LARCH-based object representations. The second phase used the analysis of LARCH and Z to identify fundamental core constructs in the languages and abstract syntax trees. These core constructs consisted of similar syntactic and semantic notions of signatures and axioms for describing a problem domain, thereby forming a canonical framework for formal object representations. This canonical framework provides a front-end for producing design refinement artifacts such as interface languages theorem proving sentences, and synthesis diagrams. The final phase demonstrated the feasibility of interface language generation by establishing an executable framework. This executable framework mapped LARCH into the SOFTWARE REFINERY(TM) Programming Environment to rapidly prototype object-oriented LARCH specifications. DTIC

IMAGE ENHANCEMENT BY EDGE-PRESERVING FILTERING
Yiu-fai Wong Nov. 1994 5 p Presented at the Institute of Electrical and Electronics Engineers (IEEE) International Conference on Image Processing, Austin, TX, 13-16 Nov. 1994
(Contract W-7405-eng-48)
(DE95-008077; UCRL-JC-116695; CONF-9411104-3) Avail: CASI HC A01/MF A01

Image enhancement is useful when the details in an image are lost due to various reasons. It is common to subtract a mask from a given image to enhance the details. The trick is how to obtain a good mask. We describe here how an edge-preserving filter can be used to generate a mask which is smooth over areas with fine details, yet preserving most of the edges. Experiments with real images show that our scheme is very effective. DOE

A SCALABLE PARALLEL STRASSEN'S MATRIX MULTIPLY ALGORITHM FOR DISTRIBUTED MEMORY COMPUTERS
Q. Luo and J. B. Drake 1995 7 p Presented at the Symposium on Applied Computing (SAC '95), Nashville, TN, 26-28 Feb. 1995
(Contract DE-AC05-84OR-21400)
(DE95-010213; CONF-950242-2) Avail: CASI HC A02/MF A01

The authors present a scalable parallel Strassen's matrix multiply algorithm for distributed memory, message passing computers. Strassen's algorithm to multiply two N x N matrices reduces the asymptotic operation count from O(N(exp 3)) of the traditional algorithm to O(N(exp 2.81)). In a sequential implementation the Strassen's algorithm offers better performance even for relatively low order matrices. However, due to its complexity, the parallel Strassen's algorithm is less than straight forward. Here a scalable parallel Strassen's algorithm is presented and compared with several other parallel algorithms. Performances of these algorithms are tested on a 128-processor Intel iPSC/860. DOE

AN APPROACH TO AUTOMATED REASONING ABOUT OPERATIONAL SEMANTICS Research Report
A. Cant and M. A. Ozols Aug. 1994 58 p
(AD-A291127; DSTO-RR-0008; DODA-AR-008-926) Avail: CASI HC A04/MF A01

The assurance of the safety or security of critical software rests on a clear understanding of the formal semantics of the programming language used. Operational semantics is the most widely used means of formally defining a language. The need for high levels of assurance, along with the complexity of these definitions for real programming languages, means that tool support is essential for carrying out reasoning about code with respect to the language definition. In this paper, we describe a generic approach to automated reasoning about the operational semantics of programming languages. As an application of this approach, we describe the construction of an environment for reasoning about programs written in a functional subset of ML. The system we describe (called Elle) captures the formal operational semantics definition of a large subset of Standard ML within the theorem prover Isabelle, and provides some support for the verification of ML programs. Since 1976, the Software Engineering Laboratory (SEL) has been dedicated to understanding and improving the way in which one NASA organization, the Flight Dynamics Division (FDD), develops, maintains, and manages complex flight dynamics systems. The SEL is composed of three member organizations: NASA/GSFC, the University of Maryland, and Computer Sciences Corporation. During the past 18 years, the SEL's overall goal has remained the same: to improve the FDD's software products and processes in a measured manner. This requires that each development and maintenance effort be viewed, in part, as a SEL experiment which examines a specific technology or builds a model of interest for use on subsequent efforts. The SEL has undertaken many technology studies while developing operational support systems for numerous NASA spacecraft missions. Derived from text

Avail: CASI HC A03/MF A03

We need to be able to learn from past experiences so we can improve our software processes and products. The Experience Factory is an organizational structure designed to support and encourage the effective reuse of software experiences. This structure consists of two organizations which separates project development concerns from organizational concerns of experience packaging and learning. The experience factory provides the processes and support for analyzing, packaging, and improving the organization's stored experience. The project organization is structured to reuse this stored experience in its development efforts. However, a number of questions arise: What past experiences are relevant? Can they all be used (reused) on our current project? How do we take advantage of what has been learned in other parts of the organization? How do we take advantage of experience in the world-at-large? Can someone else's best practices be used in our organization with confidence? This paper describes approaches to help answer these questions. We propose both quantitative

and qualitative approaches for effectively reusing software development experiences. Derived from text

Basili (Maryland Univ., College Park, MD.) *In its* Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 35-54 (For primary document see N95-31234 11-61)

Avail: CASI HC A03/MF A03

This paper reports the preliminary results of a study of the software maintenance process in the Flight Dynamics Division (FDD) of the National Aeronautics and Space Administration/Goddard Space Flight Center (NASA/GSFC). This study is being conducted by the Software Engineering Laboratory (SEL), a research organization sponsored by the Software Engineering Branch of the FDD, which investigates the effectiveness of software engineering technologies when applied to the development of applications software. This software maintenance study began in October 1993 and is being conducted using the Quality Improvement Paradigm (QIP), a process improvement strategy based on three iterative steps: understanding, assessing, and packaging. The preliminary results represent the outcome of the understanding phase, during which SEL researchers characterized the maintenance environment, product, and process. Findings indicate that a combination of quantitative and qualitative analysis is effective for studying the software maintenance process, that additional measures should be collected for maintenance (as opposed to new development), and that characteristics such as effort, error rate, and productivity are best considered on a 'release' basis rather than on a project basis. The research thus far has documented some basic differences between new development and software maintenance. It lays the foundation for further application of the QIP to investigate means of improving the maintenance process and product in the FDD. Author

We believe that the key success elements are related to our recognition that Software Process Improvement (SPI) can and should be organized, planned, managed, and measured as if it were a project to develop a new process, analogous to a software product. We believe that our process improvements have come as the result of these key elements: use of a rigorous, detailed requirements set (Capability Maturity Model, CMM); use of a robust, yet flexible architecture (IEEE 1074); use of a SPI project, resourced and managed like other work, to produce the specifications and implement them; and development of both internal and external goals, with metrics to support them. APPLYING PROGRAM COMPREHENSION TECHNIQUES TO IMPROVE SOFTWARE INSPECTIONS

Stan Rifkin and Lionel Deimel (Deimel, Lionel, Pittsburgh, PA.) *In* NASA. Goddard Space Flight Center, Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 115-126 (For primary document see N95-31234 11-61)

Avail: CASI HC A03/MF A03

Software inspections are widely regarded as a cost-effective mechanism for removing defects in software, though performing them does not always reduce the number of customer-discovered defects. We present a case study in which an attempt was made to reduce such defects through inspection training that introduced program comprehension ideas. The training was designed to address the problem of understanding the artifact being reviewed, as well as other perceived deficiencies of the inspection process itself. Measures, both formal and informal, suggest that explicit training in program understanding may improve inspection effectiveness. Author

AN EXPERIMENT TO ASSESS THE COST-BENEFITS OF CODE INSPECTIONS IN LARGE SCALE SOFTWARE DEVELOPMENT

A. Porter, H. Siy, C. A. Toman (Bell Telephone Labs., Inc., Naperville, IL.), and L. G. Votta (Bell Telephone Labs., Inc., Naperville, IL.) *In* NASA. Goddard Space Flight Center, Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 127-150 (For primary document see N95-31234 11-61)

(Grant NAG5-123)

Avail: CASI HC A01/MF A03

This experiment (currently in progress) is designed to measure costs and benefits of different code inspection methods. It is being performed with a real development team writing software for a commercial product. The dependent variables for each code unit's inspection are the elapsed time and the number of defects detected. We manipulate the method of inspection by randomly assigning reviewers, varying the number of reviewers and the number of teams, and, when using more than one team, randomly assigning author repair and non-repair of detected defects between code inspections. After collecting and analyzing the first 17 percent of the data, we have discovered several interesting facts about reviewers, about the defects recorded during reviewer preparation and during the inspection collection meeting, and about the repairs that are eventually made. (1) Only 17 percent of the defects that reviewers record in their preparations are true defects that are later repaired. (2) Defects recorded at the inspection meetings fall into three categories: 18 percent false positives requiring no author repair, 57 percent soft maintenance where the author makes changes only for readability or code standard enforcement, and 25 percent true defects requiring repair. (3) The median elapsed calendar time for code inspections is 10 working days - 8 working days before the collection meeting and 2 after. (4) In the collection meetings, 31 percent of the defects discovered by reviewers during preparation are suppressed. (5) Finally, 33 percent of the true defects recorded are discovered at the collection meetings and not during any reviewer's preparation. The results to date suggest that inspections with two sessions (two different teams) of

two reviewers per session (2sX2p) are the most effective. These two-session inspections may be performed with author repair or with no author repair between the two sessions. We are finding that the two-session, two-person with repair (2sX2pR) inspections are the most expensive, taking 15 working days of calendar time from the time the code is ready for review until author repair is complete, whereas two-session, two-person with no repair (2sX2pN) inspections take only 10 working days, but find about 10 percent fewer defects. A PROCESS IMPROVEMENT MODEL FOR SOFTWARE VERIFICATION AND VALIDATION

John Callahan and George Sabolish *In* NASA. Goddard Space Flight Center, Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 151-170 (For primary document see N95-31234 11-61)
(Contract NCCw-0040)
Avail: CASI HC A03/MF A03

We describe ongoing work at the NASA Independent Verification and Validation (IV&V) Facility to establish a process improvement model for software verification and validation (V&V) organizations. This model, similar to those used by some software development organizations, uses measurement-based techniques to identify problem areas and introduce incremental improvements. We seek to replicate this model for organizations involved in V&V on large-scale software development projects such as EOS and space station. At the IV&V Facility, a university research group and V&V contractors are working together to collect metrics across projects in order to determine the effectiveness of V&V and improve its application. Since V&V processes are intimately tied to development processes, this paper also examines the repercussions for development organizations in large-scale efforts. Author

LEVERAGING OBJECT-ORIENTED DEVELOPMENT AT AMES

Greg Wenneson and John Connell *In* NASA. Goddard Space Flight Center, Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 173-190 (For primary document see N95-31234 11-61)
Avail: CASI HC A03/MF A03

This paper presents lessons learned by the Software Engineering Process Group (SEPG) from results of supporting two projects at NASA Ames using an Object Oriented Rapid Prototyping (OORP) approach supported by a full featured visual development environment. Supplemental lessons learned from a large project in progress and a requirements definition are also incorporated. The paper demonstrates how productivity gains can be made by leveraging the developer with a rich development environment, correct and early requirements definition using rapid prototyping, and earlier and better effort estimation and software sizing through object-oriented methods and metrics. Although the individual elements of OO methods, RP approach and OO metrics had been used on other separate projects, the reported projects were the first integrated usage supported by a rich development environment. Overall the approach used was twice as productive (measured by hours per OO Unit) as a C++ development. Author

LESSONS LEARNED IN TRANSITIONING TO AN OPEN SYSTEMS ENVIRONMENT

Dillard E. Boland, David S. Green, and Warren L. Steger *In* NASA. Goddard Space Flight Center, Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 191-210 (For primary document see N95-31234 11-61)
Avail: CASI HC A03/MF A03

Software development organizations, both commercial and governmental, are undergoing rapid change spurred by developments in the computing industry. To stay competitive, these organizations must adopt new technologies, skills, and practices quickly. Yet even for an organization with a well-developed set of software engineering models and processes, transitioning to a new technology can be expensive and risky. Current industry trends are leading away from traditional mainframe environments and toward the workstation-based, open systems world. This paper presents the experiences of software engineers on three recent projects that pioneered open systems development for NASA's Flight Dynamics Division of the Goddard Space Flight Center (GSFC). LESSONS LEARNED IN DEPLOYING SOFTWARE ESTIMATION TECHNOLOGY AND TOOLS

Nikki Panlilio-Yap and Danny Ho *In* NASA. Goddard Space Flight Center, Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 211-228 (For primary document see N95-31234 11-61)
Avail: CASI HC A03/MF A03

Developing a software product involves estimating various project parameters. This is typically done in the planning stages of the project when there is much uncertainty and very little information. Coming up with accurate estimates of effort, cost, schedule, and reliability is a critical problem faced by all software project managers. The use of estimation models and commercially available tools in conjunction with the best bottom-up estimates of software-development experts enhances the ability of a product development group to derive reasonable estimates of important project parameters. This paper describes the experience of the IBM Software Solutions (SWS) Toronto Laboratory in selecting software estimation models and tools and deploying their use to the laboratory's product development groups. It introduces the SLIM and COSTAR products, the software estimation tools selected for deployment to the product areas, and discusses the rationale for their selection. The paper also describes the mechanisms used for technology injection and tool deployment, and concludes with a discussion of important lessons learned in the technology and tool insertion process. EXPERIENCE REPORT: USING FORMAL METHODS FOR REQUIREMENTS ANALYSIS OF CRITICAL SPACECRAFT SOFTWARE

Robyn R. Lutz and Yoko Ampo (Nippon Electric Co. Ltd., Tokyo, Japan.) *In* NASA. Goddard Space Flight Center, Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 231-248 (For primary document see N95-31234 11-61)
Avail: CASI HC A03/MF A03

Formal specification and analysis of requirements continues to gain support as a method for producing more reliable software. However, the introduction of formal methods to a large software project is difficult, due in part to the unfamiliarity of the specification languages and the lack of graphics. This paper reports results of an investigation into the effectiveness of formal methods as an aid to the requirements analysis of critical, system-level fault-protection software on a spacecraft currently under development. Our experience indicates that formal specification and analysis can enhance the accuracy of the requirements and add assurance prior to design development in this domain. The work described here is part of a larger, NASA-funded research project whose purpose is to use formal-methods techniques to improve the quality of software in space applications. The demonstration project described here is part of the effort to evaluate experimentally the effectiveness of supplementing traditional engineering approaches to requirements specification with the more rigorous specification and analysis available with formal methods.

EXPERIMENTAL CONTROL IN SOFTWARE RELIABILITY CERTIFICATION

Carmen J. Trammell and Jesse H. Poore *In* NASA. Goddard Space Flight Center, Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 249-264 (For primary document see N95-31234 11-61)
Avail: CASI HC A03/MF A03

There is growing interest in software 'certification', i.e., confirmation that software has performed satisfactorily under a defined certification protocol. Regulatory agencies, customers, and prospective reusers all want assurance that a defined product standard has been met. In other industries, products are typically certified under protocols in which random samples of the product are drawn, tests characteristic of operational use are applied, analytical or statistical inferences are made, and products meeting a standard

are 'certified' as fit for use. A warranty statement is often issued upon satisfactory completion of a certification protocol. This paper outlines specific engineering practices that must be used to preserve the validity of the statistical certification testing protocol. The assumptions associated with a statistical experiment are given, and their implications for statistical testing of software are described. Derived from text

GENERALIZED IMPLEMENTATION OF SOFTWARE SAFETY POLICIES
John C. Knight and Kevin G. Wika *In* NASA. Goddard Space Flight Center, Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 265-280 (For primary document see N95-31234 11-61)
(Grants NAG1-1123; NSF CCR-92-13427)
Avail: CASI HC A03/MF A03

As part of a research program in the engineering of software for safety-critical systems, we are performing two case studies. The first case study, which is well underway, is a safety-critical medical application. The second, which is just starting, is a digital control system for a nuclear research reactor. Our goal is to use these case studies to permit us to obtain a better understanding of the issues facing developers of safety-critical systems, and to provide a vehicle for the assessment of research ideas. The case studies are not based on the analysis of existing software development by others. Instead, we are attempting to create software for new and novel systems in a process that ultimately will involve all phases of the software lifecycle. In this abstract, we summarize our results to date in a small part of this project, namely the determination and classification of policies related to software safety that must be enforced to ensure safe operation. We hypothesize that this classification will permit a general approach to the implementation of a policy enforcement mechanism.

This paper presents a quantitative comparison of corrective and perfective software maintenance activities. The comparison utilizes basic data collected throughout the maintenance process. The data collected are extensive and allow the impact of both types of maintenance to be quantitatively evaluated and compared. Basic statistical techniques test relationships between and among process and product data. The results show interesting similarities and important differences in both process and product characteristics. Author

DOES SOFTWARE DESIGN COMPLEXITY AFFECT MAINTENANCE EFFORT?
Andreas Epping and Christopher M. Lott (Kaiserslautern Univ., Germany.) *In* NASA. Goddard Space Flight Center, Proceedings of the 19th Annual Software Engineering Workshop Dec. 1994 p 297-313 (For primary document see N95-31234 11-61)
Avail: CASI HC A03/MF A03

The design complexity of a software system may be characterized within a refinement level (e.g., data flow among modules), or between refinement levels (e.g., traceability between the specification and the design). We analyzed an existing set of data from NASA's Software Engineering Laboratory to test whether changing software modules with high design complexity requires more personnel effort than changing modules with low design complexity. By analyzing variables singly, we identified strong correlations between software design complexity and change effort for error corrections performed during the maintenance phase. By analyzing variables in combination, we found patterns which identify modules in which error corrections were costly to perform during the acceptance test phase. Author

Sodabot: A SOFTWARE AGENT ENVIRONMENT AND CONSTRUCTION SYSTEM M.S. Thesis
Michael H. Coen Jun. 1994 80 p
(Contract N00014-91-J-4038; NSF IRI-93-57761)
(AD-A290056; AI-TR-1493) Avail: CASI HC A05/MF A01

This thesis presents SodaBot, a general-purpose software agent user-environment and construction system. Its primary component is the basic software agent - a computational framework for building agents which is essentially an agent operating system. We also present a new language for programming the basic software agent whose primitives are designed around human-level descriptions of agent ac tivity. Via this programming language, users can easily implement a wide-range of typical software agent applications, e.g. personal on-line assistants and meeting scheduling agents. The SodaBot system has been implemented and tested, and its description comprises the bulk of this thesis. DTIC

This work discusses accomplishments obtained from the design and prototype development of a computer-aided inspection process planning system for the dimensional measurement of manufactured parts. The system, IPPEX (Inspection Planning and Programming EXpert), is a knowledge-based system. This prototype system applies intelligence techniques and implements an advanced product definition modeling system. The IPPEX framework is based on a functional architecture designed for the purpose of producing inspection process plans, CMM part programs, and support information. The IPPEX conceptual prototype system selects the appropriate CMM, identifies the measurable surfaces, suggests probing point determination, performs inspection work element planning, and creates an initial Dimensional Measurement Interface Specification part program, all for a specific workpiece. This work describes the IPPEX system, its functional architecture, system architecture, system approach, product modeling environment, inspection features, inspection knowledge, hierarchical planning strategy, user interface formats, and other fundamental issues related to inspection planning and part programming for CMMs. Finally, this document describes research that will contribute toward furthering the development of automated inspection planning, advancing product modelling systems with application accessible tolerances, and defining standard dimensional inspection techniques and methodologies. QUASI-NEWTON UPDATING FOR LARGE SCALE NONLINEAR SYSTEMS Final Report, 1 Jul. 1991 - 30 Jun. 1994
H. F. Walker 1994 10 p
(Grant AF-AFOSR-0294-91)
(AD-A292776; AFOSR-95-0209TR) Avail: CASI HC A02/MF A01

Research was directed toward developing robust and efficient iterative methods for large-scale systems of nonlinear algebraic equations, especially discretizations of continuous problems such as partial differential and integral equations. The specific goal was to develop effective Newton iterative methods (implementations of Newton's method using iterative linear algebra methods) and improved iterative linear solvers for use in them. A theoretically sound abstract framework was formulated. Significant progress was made toward a well-developed software implementation. Useful advances were made in the development and understanding of iterative linear solvers. DTIC

INTELLIGENT FINITE ELEMENT SUBMODELING OF MULTICHIP MODULES FOR RELIABILITY ANALYSIS Final Technical Report, Jan. 1993 - Jan. 1994
Ian R. Grosse, Michael Sheehy, Prasanna Katragadda, and Shankar Raman Dec. 1994 122 p
(Contract F30602-93-C-0040)
(AD-A292911; RL-TR-94-218) Avail: CASI HC A06/MF A02

Modeling methodologies were developed, implemented, and tested for both rapid thermal finite element analysis of small-scale integrated circuit features in MCM's, and for thermal stress finite element analysis of chip-to-substrate interconnects. A three-step sequential analysis methodology was developed that is initiated with a macroscope thermal analysis of the entire MCM package. The macroscope finite element thermal analysis is then followed by two successive finite element thermal submodels of the hottest die first and then of the hottest die microfeature. In this manner, the thermal analysis process mathematically zooms into the hottest IC microfeature without resorting to supercomputer-size finite element models of the MCM. A two-step sequential thermal-stress finite element submodeling analysis procedure was also developed for thermally induced stress analysis of the most highly stressed wirebond or TAB interconnect in an MCM package. For automation purposes, both the IC thermal submodeling and the interconnect elastostatic submodeling methodologies were implemented into an existing blackboard-based, object-oriented MCM software design tool called the Intelligent MCM Analysis (IMCMA). ANALYSIS OF SYMBOLIC PARAMETER MODELS Final Technical Report, 15 Feb. 1991 - 14 Feb. 1993
Herbert A. Simon, Thad Polk, and Kurt Vanlehn 16 Mar. 1995 34 p
(Contract N00014-91-J-1529)
(AD-A292916) Avail: CASI HC A03/MF A01

Model-fitting, the problem of finding parameter settings that cause a model to fit given data as closely as possible, is a hard but important problem in cognitive science in general, and in cognitive diagnosis in particular. Efficient solutions have been found for certain types of model-fitting problems (e.g., linear and integer programming) that involve specific types of parameters (usually continuous) and models (usually linear).

But these techniques usually do not apply to computational cognitive models whose parameters are often discrete and symbolic and whose internal workings must be treated as a black box for the purposes of fitting. We have constructed ASPM (Analysis of Symbolic Parameter Models), a suite of computational tools for fitting and analyzing such symbolic parameter models. We have shown how it can be used to fit and analyze computational models with well over 10 billion combinations of parameter settings. We have made a good start towards making ASPM robust and user friendly in preparation for releasing it for public use. DTIC

THE OCCURRENCE OF CONTINUATION PARAMETERS IN CPS TERMS
Olivier Danvy and Frank Pfenning Feb. 1995 24 p
(Grant NSF CCR-93-33383)
(AD-A292952; CMU-CS-95-121) Avail: CASI HC A03/MF A01

We prove an occurrence property about formal parameters of continuations in Continuation-Passing Style (CPS) terms that have been automatically produced by CPS transformation of pure, call-by-value lamda-terms. Essentially, parameters of continuations obey a stack-like discipline. This property was introduced, but not formally proven, in an earlier work on the Direct-Style transformation (the inverse of the CPS transformation). The proof has been implemented in Elf, a constraint logic programming language based on the logical framework LF. In fact, it was the implementation that inspired the proof. Thus this note also presents a case study of machine-assisted proof discovery. DTIC

THE REMAINDER FORM AND THE CORD-SLOPE FORM IN GLOBAL OPTIMIZATION WITH INTERVAL METHODS Ph.D. Thesis
Junjie Xiong 1993 124 p
Avail: Univ. Microfilms Order No. DA9412704

The dissertation is devoted to the study of algorithms for global optimization using interval methods. It consists of two parts. In part one, global optimization of a univariate function on an interval is studied. This function is assumed to be three times differentiable. The cord-slope form of a function is introduced and is used to eliminate parts of the initial interval which cannot contain the global optimum. Twelve test problems are solved and computational results are compared with those of Eldon Hansen's algorithm. The algorithm is further extended locate all the global optima of the function on the interval as well as to the case where the problem is constrained. Then, the cord-slope form has a special structure which leads to a more efficient algorithm. It is proved also that when natural extension form is used for evaluating the bounds of the slope, the interval arithmetic algorithm is equivalent to a decomposition-based global optimization algorithm (GOP) proposed by Floudas and Visweswaran. Finally, an exact version of the Alienor method is developed. In the original version of Alienor method proposed by Cherruault and Guillez, Alienor transformation is used to approximate an n-dimensional function by a univariate function; then the globally optimal solution of the univariate problem can be used as an approximate solution of the original problem. We explore what conditions have to be imposed on the parameters to make the algorithm exact, i.e. to guarantee that the globally optimal value found is at most epsilon away from the true globally optimal value and apply the cord-slope form algorithm to solve the resulting univariate problem. In part two the multivariate global optimization problem is studied. The first case considered is where the objective function is an indefinite quadratic function and only range constraints are present. The algorithm is of branch-and-bound type and branching is done according to the sign of the derivatives. Comparison is made with an interval arithmetic implementation. The algorithm is then applied to find the range of general functions (three times differentiable) using the remainder form proposed by Cornelius and Lohner and comparison is made with the bounds found by using natural extension directly. An algorithm is also proposed for the general case when the objective function is a nonlinear differentiable function and nonlinear constraints are present. Dissert. Abstr.

EFFECTIVENESS OF AN ELECTRONIC PERFORMANCE SUPPORT SYSTEM FOR USE WITH COMPUTER-AIDED DESIGN SOFTWARE Final Report
Doris S. Shaw, Thomas Mack, Julie L. Webster, Daniel J. Nix, and Donald K. Hicks Jan. 1995 70 p
(DA Proj. 4A1-62784-AT-41)
(AD-A293757; CERL-FF-95/06) Avail: CASI HC A04/MF A01

Although Bentley Systems, Inc. (BSI) CAD, a computer-aided design program used in many U.S. Army Corps of Engineers offices, can produce the detailed documents necessary for planning, review, construction, and management of a facility, such software requires extensive training. Allocating the time and resources to learn such computer-based technology is a pressing productivity concern in both government and commercial settings. The U.S. Army Construction Engineering Research Laboratories (USACERL) has studied the use of Computer-Aided Instruction (CAI) to train architects and engineers to use many types of automated systems. Development of the Mentor Hypertext Electronic Performance Support System can help meet this need for cost-effective CAD training done within the context of current working projects, by incorporating embedded online instruction into MicroStation CAD software. This study enhanced the Mentor CAI system for use with MicroStation software and tested the system with users representing a range of disciplines and CAD expertise. At the end of the test period, a survey was administered to determine their use of the system, attitudes, learning preferences, and reactions to the program. DTIC

A TWO-DIMENSIONAL FINITE DIFFERENCE ALGORITHM ON THE KSR1 Final Report, Jul. 1993 - Sep. 1994
Christopher S. Kenyon Apr. 1995 21 p Limited Reproducibility: More than 20% of this document may be affected by poor print
(AD-A293576; ARL-MR-213) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Executing electromagnetic pulse (EMP) codes on the fastest possible computers has been a goal of research in recent years, because it would allow new classes of EMP problems to be solved. A new kind of supercomputer architecture has emerged in recent years, called a massively parallel processor (MPP). This study examines the performance of a two-dimensional finite difference algorithm, a Yee algorithm, which is a major part of some EMP codes, on an MPP computer, the KSR1. Performance of the Yee algorithm, using a mesh of 2000 x 2000, scales roughly in proportion to the number of processors, up to about 32. The maximum performance of the Yee algorithm on the KSR1 was 161 Mflops using 50 processors, or 5.8 times faster than on a 50-MHz IBM RS/6000 workstation. For a 2000 x 2000 matrix multiply test, representative of an important algorithm in moment methods for solving electromagnetic problems, the peak performance on the KSR1 was 279 Mflops with 32 processors. This matrix multiply ran about three times faster than on the IBM workstation. It was concluded that the modest gains found here were insufficient to warrant a full port of a large EMP code to the KSR1. DTIC

SPECTRAL METHODS AND SUM ACCELERATION ALGORITHMS Final Report, May 1991 - Aug. 1994
John Boyd Mar. 1995 5 p
(Contract DE-FG02-91ER-25109)
(DE95-009689; DOE/ER-25109/T1) Avail: CASI HC A01/MF A01

The principle investigator pursued his investigation of numerical algorithms during the period of the grant. The attached list of publications is so lengthy that it is impossible to describe them in detail. However, the author calls attention to the four articles on sequence acceleration and fourteen more on spectral methods, which fulfill the goals of the original proposal. He also continued his research on nonlinear waves, and wrote a dozen papers on this, too. DOE

FINITE-SAMPLE BASED LEARNING ALGORITHMS FOR FEEDFORWARD NETWORKS
N. S. V. Rao, V. Protopopescu, R. C. Mann, E. M. Oblow, and S. S. Iyengar (Louisiana State Univ., Baton Rouge, LA.) 1995 12 p Presented at the Symposium on Theory of Computing, Las Vegas, NV, 29 May - 1 Jun. 1995
(Contract DE-AC05-84OR-21400)
(DE95-009123; CONF-9505145-2) Avail: CASI HC A03/MF A01

We discuss two classes of convergent algorithms for learning continuous

functions (and also regression functions) that are represented by FeedForward Networks (FFN). The first class of algorithms, applicable to networks with unknown weights located only in the output layer, is obtained by utilizing the potential function methods of Aizerman et al. The second class, applicable to general feedforward networks, is obtained by utilizing the classical Robbins-Monro style stochastic approximation methods. Conditions relating the sample sizes to the error bounds are derived for both classes of algorithms using martingale-type inequalities. For concreteness, the discussion is presented in terms of neural networks, but the results are applicable to general feedforward networks, in particular to wavelet networks. The algorithms can also be directly applied to concept learning problems. A main distinguishing feature of the this work is that the sample sizes are based on explicit algorithms rather than information-based methods. DOE

NETWORK USER'S GUIDE
P. W. McGrady Dec. 1994 135 p
(Contract DE-AC05-84OR-21400)
(DE95-009185; ORNL/TM-12867) Avail: CASI HC A07/MF A02

NETWORK is a FORTRAN code used to model process flow systems in the gaseous diffusion plants at Portsmouth, Ohio and Paducah, Kentucky, operated by the United States Enrichment Corporation. It can handle a wide range of components and several different types of controllers. NETWORK can be run in either a steady-state mode or a transient mode. In the transient mode many different types of perturbations may be modeled. It is currently being used to model taking a cell off-stream in a gaseous diffusion plant. A brief description of the code is given, and process equipment models and input data are discussed. DOE

A SIMPLE AND EFFICIENT PROCEDURE FOR POLYHEDRAL ASSEMBLY PARTITIONING UNDER INFINITESIMAL MOTIONS
L. J. Guibas, D. Halperin, J. C. Latombe (Stanford Univ., CA.), Hirohisa Hirukawa (Ministry of International Trade and Industry, Tsukuba, Japan.), and R. H. Wilson 1994 8 p Presented at the 1995 International Conference on Robotics and Automation, Nagoya, Japan, 21-27 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-009838; SAND-94-3129C; CONF-9505193-4) Avail: CASI HC A02/MF A01

The authors study the following problem: given a collection A of polyhedral parts in 3D, determine whether there exists a subset S of the parts that can be moved as a rigid body by an infinitesimal translation and rotation, without colliding with the rest of the parts, A/S. A negative result implies that the object whose constituent parts are the collection A cannot be taken apart with two hands. A positive result, together with the list of movable parts in S and a direction of motion for S, can be used by an assembly sequence planner. This problem has attracted considerable attention within and outside the robotics community. They devise an efficient algorithm to solve this problem. The solution is based on the ability to focus on selected portions of the tangent space of rigid motions and efficiently access these portions. The algorithm is complete (in the sense that it is guaranteed to find a solution if one exists), simple, and improves significantly over the best previously known solutions. The authors report experimental results with an implementation of their algorithm. DOE

AN ANALYSIS OF HIERARCHICAL GENETIC PROGRAMMING
Justinian P. Rosca Mar. 1995 27 p Limited Reproducibility: More than 20% of this document may be affected by poor print
(Contract MDA972-92-J-1012; NSF IRI-94-06481)
(AD-A293964; TR-566) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

Hierarchical genetic programming (HGP) approaches rely on the discovery, modification, and use of new functions to accelerate evolution. This paper provides a qualitative explanation of the improved behavior of HGP, based on an analysis of the evolution process from the dual perspective of diversity and causality. From a static point of view, the use of an HGP approach enables the manipulation of a population of higher diversity programs. Higher diversity increases the exploratory ability of the genetic search process, as demonstrated by theoretical and experimental fitness distributions and expanded structural complexity of individuals. From a dynamic point of view, this report analyzes the causality of the crossover operator. Causality relates changes in the structure of an object with the effect of such changes, i.e. changes in the properties or behavior of the object. The analyses of crossover causality suggests that HGP discovers and exploits useful structures in a bottom-up, hierarchical manner. Diversity and causality are complementary, affecting exploration and exploitation in genetic search. Unlike other machine learning techniques that need extra machinery to control the tradeoff between them, HGP automatically trades off exploration and exploitation. DTIC

PENELOPE REFERENCE MANUAL: VERSION 3-3 (C001). INCLUDES LARCH/Ada SPECIFICATION MANUAL FOR SEQUENTIAL Ada (C002)
Carla Marceau 2 Sep. 1994 155 p
(Contract F19628-93-C-0130)
(AD-A289828; STARS-AC-C001/001/00) Avail: CASI HC A08/MF A02

Penelope is an interactive environment that helps its user to develop and verify programs written in a rich subset of sequential Ada. Penelope is well-suited to developing programs in the goal-directed style advocated by Gries and Dijkstra. In this style the programmer develops a program from a specification in a way that ensures the program will meet the specification. Of course, Penelope can also be used to verify previously written programs. With Penelope, it is often possible to modify a verified program and verify the modified version with minimal effort by replaying and modifying the original program's proof. DTIC

IMAGE REPRESENTATION USING FAST ALGORITHMS BASED ON THE ZAK TRANSFORM Final Technical Report, Oct. 1990 - Mar. 1994
George A. Geri and Izidor C. Gertner Dec. 1994 124 p Prepared in cooperation with City College of the City Univ. of New York, NY
(Contract F33615-90-C-0006)
(AD-A293416; AL/HR-TR-1994-0106) Avail: CASI HC A06/MF A01

Flight simulator imagery is often made up of natural scenes whose characteristics are not constant across the image. This property suggests that such imagery can be most efficiently represented by spectral techniques that use spatially localized basis functions. This report describes techniques for decomposing full gray-scale images into a joint position/spatial-frequency domain using bases derived from various window functions. The first set of window functions consists of the hermite functions which are related to gaussian derivatives. The second set is based on a new window function that is obtained from a weighted ZAK transform and that provides good localization properties and stable computation. The third set is based on a localized cosine function and allows images to be decomposed using real numbers only. All of the techniques described provide a framework for filtering images in a position-varying manner. For all the basis functions described here, image generation from combined position and spatial-frequency information involves a computationally intensive four-dimensional summation. By an application of the Zak Transform, we are able to replace this summation with a fast Fourier transform, significantly reducing the complexity of the computation. DTIC

PORK OBJECT SYSTEM PROGRAMMER'S GUIDE
Ora Lassila Apr. 1995 68 p
(Contract F30602-90-C-0119)
(AD-A293596; CMU-RI-TR-95-12) Avail: CASI HC A04/MF A01

Pork is an object system which brings a conventional object-oriented language closer to the requirements of frame-based programming. It only provides a very limited set of features (on top of the base object system itself), and aims to achieve seamless integration with conventional programming. PORK is implemented as a portable metalevel extension of the Common Lisp Object System (CLOS). It extends CLOS by adding the following concepts: (1) Named objects - These simplify debugging and linked frame model construction. Collections of named objects (called 'namespaces') can also be used as a low-level implementation vehicle for knowledge bases; (2) References to nonexisting named objects - Programs can manipulate objects that have not yet been created. This greatly simplifies definition of complex linked frame models with circular references; (3) Slots with multiple values, and a mechanism for defining an access interface; (4) Automatic updating of inverse slots. APPLICATION OF A GENETIC ALGORITHM TO OPTIMIZE STAFFING LEVELS IN SOFTWARE DEVELOPMENT M.S. Thesis

Donald C. Johnson Dec. 1994 72 p

(AD-A293725) Avail: CASI HC A04/MF A01

Human resource management is gaining recognition as being one of the core attributes of effective software project management. With the great dependency the Department of Defense (DOD) has on systems software, the development of an optimal staffing policy that minimizes overall software project costs will be very valuable. This research aims at developing such a system using a dynamic simulation model that incorporates data collected during an actual software development project. A genetic algorithm is used to arrive at a solution to this nonlinear optimization problem. The simulation model accepts varying staffing schemes supplied from the genetic algorithm allowing for the examination of the effects of the staffing schemes on total project cost. The results indicate that the system was able to obtain a solution reducing overall project costs, but at the cost of additional workdays. DTIC

GEOMETRIC MODELING FOR COMPUTER AIDED DESIGN Final Report, period ended 30 Jun. 1995

James L. Schwing and Stephen Olariu Jul. 1995 28 p

(Contract NCC1-99)

(NASA-CR-198828; NAS 1.26:198828) Avail: CASI HC A03/MF A01

The primary goal of this grant has been the design and implementation of software to be used in the conceptual design of aerospace vehicles particularly focused on the elements of geometric design, graphical user interfaces, and the interaction of the multitude of software typically used in this engineering environment. This has resulted in the development of several analysis packages and design studies. These include two major software systems currently used in the conceptual level design of aerospace vehicles. These tools are SMART, the Solid Modeling Aerospace Research Tool, and EASIE, the Environment for Software Integration and Execution. Additional software tools were designed and implemented to address the needs of the engineer working in the conceptual design environment. SMART provides conceptual designers with a rapid prototyping capability and several engineering analysis capabilities. In addition, SMART has a carefully engineered user interface that makes it easy to learn and use. Finally, a number of specialty characteristics have been built into SMART which allow it to be used efficiently as a front end geometry processor for other analysis packages. EASIE provides a set of interactive utilities that simplify the task of building and executing computer aided design systems consisting of diverse, stand-alone, analysis codes. Resulting in a streamlining of the exchange of data between programs reducing errors and improving the efficiency. EASIE provides both a methodology and a collection of software tools to ease the task of coordinating engineering design and analysis codes. Derived from text

A PROGRAMMING INTERFACE FOR APPLICATION-AWARE ADAPTATION IN MOBILE COMPUTING

Brian D. Noble, Morgan Price, and M. Satyanarayanan Feb. 1995 14 p Presented at the 2nd USENIX Symposium on Mobile and Location-Independent Computing, Ann Arbor, MI, Apr. 1995

(Contract F19628-93-C-0193)

(AD-A293107; CMU-SC-95-119) Avail: CASI HC A03/MF A01

Mobile clients face wide variations in network conditions and local resource availability when accessing remote data. Coping with this uncertainty requires the ability to retrieve and present data at varying degrees of fidelity. In this paper we present application-aware adaptation as a solution to this problem. The essence of our solution is a collaborative partnership between applications and the operating system. We describe the Odyssey API for application-aware adaptation and demonstrate its use in accessing two types of data: video and maps. DTIC

PADO: LEARNING TREE STRUCTURED ALGORITHMS FOR ORCHESTRATION INTO AN OBJECT RECOGNITION SYSTEM

Astro Teller and Manuela Veloso 10 Feb. 1995 34 p

(AD-A293109; CMU-CS-95-101) Avail: CASI HC A03/MF A01

Most artificial intelligence systems today work on simple problems and artificial domains because they rely on the accurate sensing of the task world. Object recognition is a crucial part of the sensing challenge and machine learning stands in a position to catapult object recognition into real world domains. Given that, to date, machine learning has not delivered general object recognition, we propose a different point of attack: the learning architectures themselves. We have developed a method for directly learning and combining algorithms in a new way that imposes little burden on or bias from the humans involved. This learning architecture, PADO, and the new results it brings to the problem of natural image object recognition is the focus of this report. DTIC

MONTE CARLO TESTS OF THE ELIPGRID-PC ALGORITHM

J. R. Davidson Apr. 1995 113 p

(Contract DE-AC05-84OR-21400)

(DE95-010811; ORNL/TM-12899) Avail: CASI HC A06/MF A02

The standard tool for calculating the probability of detecting pockets of contamination called hot spots has been the ELIPGRID computer code of Singer and Wickman. The ELIPGRID-PC program has recently made this algorithm available for an IBM(reg sign) PC. However, no known independent validation of the ELIPGRID algorithm exists. This document describes a Monte Carlo simulation-based validation of a modified version of the ELIPGRID-PC code. The modified ELIPGRID-PC code is shown to match Monte Carlo-calculated hot-spot detection probabilities to within +/- 5% for 319 out of 320 test cases. The one exception, a very thin elliptical hot spot located within a rectangular sampling grid, differed from the Monte Carlo-calculated probability by about 1%. These results provide confidence in the ability of the modified ELIPGRID-PC code to accurately predict hot-spot detection probabilities within an acceptable range of error. DOE

A STOCHASTIC EM ALGORITHM FOR APPROXIMATING THE MAXIMUM LIKELIHOOD ESTIMATE

J. Diebolt and E. H. S. Ip Mar. 1995 26 p
(Contract DE-AC04-94AL-85000)
(DE95-010328; SAND-95-8102) Avail: CASI HC A03/MF A01

Stochastic EM is an algorithm designed to handle missing data in statistical applications. Instead of performing the expectation step in the Expectation-Maximization (EM) algorithm, Stochastic EM impute a sample value drawn from the conditional distribution of the missing data given the parameter. This paper explains how the algorithm can be applied in statistical inference to avoid numerical integrations and presents two examples using the Stochastic EM algorithm. The first example deals with censored Weibull data and the second example deals with an empirical Bayes model that arises in educational testing. Some variants of the algorithm are also discussed. This report only treats the theory underlying the Stochastic EM briefly. The properties of the Stochastic EM estimates are dealt with in depth in a sequel of this report. DOE

ANALYSIS AND EXTENSION OF MODEL-BASED SOFTWARE EXECUTIVES M.S. Thesis, 1994
Keith E. Lewis Jan. 1995 100 p Limited Reproducibility: More than 20% of this document may be affected by poor print
(AD-A293834; AFIT/GE/ENG/95M-01) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

This research developed a comprehensive description of the simulation environment of Architect, a domain-oriented application composition system being developed at the Air Force Institute of Technology to explore new software engineering technologies. The description combines information from several previous research efforts and Architect's source code into a single, comprehensive document. A critical evaluation of the simulation environment was also performed, identifying improvements and modifications that enhance Architecture's application execution capabilities by reducing complexity and execution time. The analysis was then taken one step further and presented extensions to the current simulation environment. The extensions included investigating the feasibility of mixed-mode execution and integrating the composition of application executives with the visual system interface. DTIC

ESTIMATION IN SECOND ORDER DEPENDENCY MODEL FOR MULTIVARIATE BINARY DATA
Eddie H. S. Ip (Stanford Univ., CA.) Apr. 1995 18 p
(Contract DE-AC04-94AL-85000)
(DE95-010326; SAND-95-8100; UC-405) Avail: CASI HC A03/MF A01

This paper proposes a normal model for multivariate binary data. The normal model is an extension to the bivariate normal model for 2 x 2 contingency table proposed by Pearson. A stochastic algorithm using Gibbs sampler is developed to estimate the parameters for high dimensional binary data. The method is compared to the second order dependency Bahadur-Lazarsfeld representation of binary density. Two examples, one from psychological testing and one from medical science, are used to substantiate the above ideas. DOE

A STOCHASTIC DIFFERENCE EQUATION APPROACH TO INFERENCE WITH MISSING DATA: SOME NEW RESULTS
Eddie H. S. Ip and Jean Diebolt (Stanford Univ., CA.) Apr. 1995 25 p
(Contract DE-AC04-94AL-85000)
(DE95-010327; SAND-95-8101; UC-405) Avail: CASI HC A03/MF A01

This paper is concerned with the study of the properties of the Stochastic EM estimator. The Stochastic EM estimator is an estimator derived from an iterative algorithm which handles statistical model with missing data. The first result we obtain is on the decomposition of a general stochastic difference equation underlying the Stochastic EM iterates into an additive form. Such decomposition allows a further analysis of the Markov chain underlying the Stochastic EM algorithm. The second result indicates that the Stochastic EM estimator differs from the maximum likelihood estimate by O (1/n) where n is the sample size. It also shows that iterates derived from the additive stochastic difference equation converges to a normal distribution which is centered at the true value of the parameter as n (yields) (infinity). DOE

N95-32089# Sandia National Labs., Albuquerque, NM.
A STOCHASTIC EM ESTIMATOR IN THE PRESENCE OF MISSING DATA: THEORY AND APPLICATIONS
E. H. S. Ip (Stanford Univ., CA.) Apr. 1995 116 p
(Contract DE-AC04-94AL-85000)
(DE95-010329; SAND-95-8103) Avail: CASI HC A06/MF A02

This thesis provides a study of a Monte Carlo version of the EM (for Expectation-Maximization) algorithm for handling complex missing-data structure in which high-dimensional integrations may be involved. Assuming a parametric model for the complete data, we propose a method for imputing values for missing data and then iteratively perform direct parametric inference based on the pseudo-complete data. If the iteration converges, the result of the procedure is a sample from a stationary distribution derived from the Markov chain formed by the iterations of the parameter. This algorithm is called Stochastic EM and the estimator we propose is the mean of the stationary distribution. We provide new theoretical results on the Stochastic EM estimator. First, under an exponential family setting, we show that asymptotically the Markov chain kernel of Stochastic EM can be decomposed into an additive stochastic difference equation. This decomposition allows us to provide useful results for the asymptotic behavior of the stationary distribution under specific conditions. The next result we obtain is that the Stochastic EM estimator is close to the maximum likelihood estimate. Another result shows that asymptotically the Stochastic EM iterations converge to a normal distribution with the true parameter as its mean. Bounds are obtained for the norm of the covariance matrix. There are two examples, one from medical science and one from education to substantiate the theory. In the education example, the use of straightforward EM would require performing an overwhelmingly large number of high-dimensional numerical integrations even for a moderate sample of a thousand multivariate binary observations. EVALUATION OF DISCRETIZATION PROCEDURES FOR TRANSITION ELEMENTS IN ADAPTIVE MESH REFINEMENT
K. C. Park, Itzak Levit (Lockheed Missiles and Space Co., Palo Alto, CA.), and Gary M. Stanley (Lockheed Missiles and Space Co., Palo Alto, CA.) May 1991 16 p
(Grant NAG1-756)
(NASA-CR-199037; NAS 1.26:199037; CU-CSSC-91-15) Avail: CASI HC A03/MF A01

Three transition interpolation schemes for use in h-or r-refinement have been analyzed in terms of accuracy, implementation ease and extendability. They include blending-function interpolation, displacement averaging, and strain matching at discrete points along the transition edge lines. The results suggest that the choice of matching depends strongly on the element formulations, (viz. displacement or assumed strain, etc.) and mesh refinement criteria employed, and to a lesser extent the choice of computer architecture (serial vs. parallel) and the equation solution procedures. A recommended pairing of some of the elements with the choice factors is suggested.

A SURVEY OF THE CORE-CONGRUENTIAL FORMULATION FOR GEOMETRICALLY NONLINEAR TL FINITE ELEMENTS
Carlos A. Felippa, Luis A. Crivelli, and Bjorn Haugen May 1994 58 p
Submitted for publication in Archives of Computational Methods in Engineering
(Contract NAG1-756; NAG3-1273; F49620-87-C-0074; NSF ASC-92-17394)
(NASA-CR-199044; NAS 1.26:199044; CU-CAS-94-08) Avail: CASI HC A04/MF A01

This article presents a survey of the core-congruential formulation (CCF) for geometrically nonlinear mechanical finite elements based on the total Lagrangian (TL) kinematic description. Although the key ideas behind the CCF can be traced back to Rajasekaran and Murray in 1973, it has not subsequently received serious attention. The CCF is distinguished by a two-phase development of the finite element stiffness equations. The initial phase developed equations for individual particles. These equations are expressed in terms of displacement gradients as degrees of freedom. The second phase involves congruential-type transformations that eventually binds the element particles of an individual element in terms of its

node-displacement degrees of freedom. Two versions of the CCF, labeled direct and generalized, are distinguished. The direct CCF (DCCF) is first described in general form and then applied to the derivation of geometrically nonlinear bar, and plane stress elements using the Green-Lagrange strain measure. The more complex generalized CCF (GCCF) is described and applied to the derivation of 2D and 3D Timoshenko beam elements. Several advantages of the CCF, notably the physically clean separation of material and geometric stiffnesses, and its independence with respect to the ultimate choice of shape functions and element degrees of freedom, are noted. Application examples involving very large motions solved with the 3D beam element display the range of applicability of this formulation, which transcends the kinematic limitations commonly attributed to the TL description. A TRANSIENT FETI METHODOLOGY FOR LARGE-SCALE PARALLEL IMPLICIT COMPUTATIONS IN STRUCTURAL MECHANICS

Charbel Farhat, Luis Crivelli, and Francois-Xavier Roux (Office National d'Etudes et de Recherches Aerospatiales, Chatillon, France.) Nov. 1992 45 p

(Grant NAG1-756)

(NASA-CR-199040; NAS 1.26:199040; CU-CSSC-92-15) Avail: CASI HC A03/MF A01

Explicit codes are often used to simulate the nonlinear dynamics of large-scale structural systems, even for low frequency response, because the storage and CPU requirements entailed by the repeated factorizations traditionally found in implicit codes rapidly overwhelm the available computing resources. With the advent of parallel processing, this trend is accelerating because explicit schemes are also easier to parallelize than implicit ones. However, the time step restriction imposed by the Courant stability condition on all explicit schemes cannot yet -- and perhaps will never -- be offset by the speed of parallel hardware. Therefore, it is essential to develop efficient and robust alternatives to direct methods that are also amenable to massively parallel processing because implicit codes using unconditionally stable time-integration algorithms are computationally more efficient when simulating low-frequency dynamics. Here we present a domain decomposition method for implicit schemes that requires significantly less storage than factorization algorithms, that is several times faster than other popular direct and iterative methods, that can be easily implemented on both shared and local memory parallel processors, and that is both computationally and communication-wise efficient. The proposed transient domain decomposition method is an extension of the method of Finite Element Tearing and Interconnecting (FETI) developed by Farhat and Roux for the solution of static problems. Serial and parallel performance results on the CRAY Y-MP/8 and the iPSC-860/128 systems are reported and analyzed for realistic structural dynamics problems. These results establish the superiority of the FETI method over both the serial/parallel conjugate gradient algorithm with diagonal scaling and the serial/parallel direct method, and contrast the computational power of the iPSC-860/128 parallel processor with that of the CRAY Y-MP/8 system. ASSESSMENT OF COMPUTER AIDS DURING COMMUNICATION EXERCISE 1991 [UTVAERDERING AV DATORSTOED UNDER SOE 1991 IAKTTAGEL SER AV DATORSTOEDETS ANVAENDNING OCH FUNKTION]

I. Alm, T. Naeslund, and T. Nordqvist Oct. 1994 22 p In SWAHILI

(PB95-211462; FOA-R-94-00065-5.5-SE) Avail: Issuing Activity (National Technical Information Service (NTIS))

This study describes functions and applications of three computer systems used during Communication exercise '91, and summarizes an account of two inquiries about the computer systems. The observations, interviews, and the inquiries indicate that the users of the computer system were insufficiently educated and trained with respect to pragmatic use of the systems. The use of the systems was both cautious and fumbling. Moreover, the integration of the different applications was insufficient, and hence, the ability to utilize the systems efficiently was reduced during these circumstances. It seems that expectations about what the system can do were somewhat optimistic. NTIS

GIGABIT TESTBED RESEARCH PROJECT Final Report, 1 Aug. 1992 - 31 Dec. 1994

D. Ferrari, R. Katz, and J. Ousterhout 1995 11 p

(Contract DE-FG03-92ER-25135)

(DE95-010728; DOE/ER-25135/T1) Avail: CASI HC A03/MF A01

This project was aimed at investigating some of the computer and communication technologies on which imaging applications are being and will be built (high-speed networks, quality-preserving continuous-media protocols, large and fast storage servers), and demonstrating the use of those technologies in some energy-related applications. It complemented and provided useful technological underpinnings to several Lawrence Berkeley Laboratory research efforts supported by DOE, in particular to

High Speed Distributing of Network-based Video Microscopy and Supercomputer Access Techniques. DOE

This paper presents the results and lessons learned from trial usage of the Software Engineering Institute's (SEI) Software Process Framework (SPF). The SPF was used to check consistency of the Cleanroom Software Engineering (CSE) process against the SEI Capability Maturity Model (CMM) for software. The trial usage was done for a STARS (Software Technology for Adaptable, Reliable Systems) supported software development project, Improved Mortar Ballistic Computer (IMBC), at the US Army's Picatinny Arsenal Life Cycle Software Engineering Center (LCSEC). USING PROCESS TO INTEGRATE SOFTWARE ENGINEERING ENVIRONMENTS (SOFTWARE TECHNOLOGY FOR ADAPTABLE, RELIABLE SYSTEMS (STARS) PROGRAM)
Richard L. Randall and William H. Ett 16 Jan. 1995 65 p
(Contract F19628-93-C-0129)
(AD-A292816) Avail: CASI HC A04/MF A01

A layered architecture is fundamental to the megaprogramming approach being followed by the Air Force/STARS Demonstration Project, as engineers develop the Space Command and Control Architectural Infrastructure application for NORAD and USSPACECOM. This layering strategy also applies to the Software Engineering Environment (SEE) being used to support the application development. This paper focuses on one particular SEE layer: a layer that leverages one of an organization's most valued assets - its process - and uses it as a basis for SEE integration. The activity to produce and use the PSE has yielded useful lessons learned which can guide other organizations as they pursue their own process-driven SEE's. DTIC

SWSC DOMAIN ENGINEERING EXPERIENCE (SOFTWARE TECHNOLOGY FOR ADAPTABLE, RELIABLE SYSTEMS (STARS) PROGRAM)
Brian Bulet 15 Jan. 1995 51 p
(Contract F19628-93-C-0129)
(AD-A292817) Avail: CASI HC A04/MF A01

The Space and Warning Systems Center (SWSC) in Colorado Springs maintains and develops Command and Control Systems for NORAD, USSPACECOM, and AFSPC. Twenty-seven 'stovepipe' systems imbedding twenty-four languages and ten millions lines of code make for a maintenance nightmare and for a fertile ground for megaprogramming, or product line software reuse. At the SWSC, the SCAI (Space Command and Control Architectural Infrastructure) project has been instituting architecture-based, product line software reuse for the past two years. The SCAI project is the STARS/Loral/Air Force Megaprogramming Demonstration Project out of ARPA. This paper presents the lessons learned in developing and using a domain architecture, a domain architecture framework, and a domain engineering process, while developing a SCAI space surveillance application. INTEGRATING A SEE FOR MEGAPROGRAMMING: LESSONS LEARNED (SOFTWARE TECHNOLOGY FOR ADAPTABLE, RELIABLE SYSTEMS (STARS) PROGRAM)
Richard L. Randall, Robert K. Ekman, Gary S. Turner, and Scott Kent 17 Jan. 1995 59 p
(Contract F19628-93-C-0129)
(AD-A292838) Avail: CASI HC A04/MF A01

The objective of megaprogramming technology is to make possible a software product-line organization - one that can produce related systems cheaper, better, and faster by using a methodical process based on a common architectural approach. To apply such state-of-the-art technology, a product-line organization needs a common software engineering environment (SEE) that is itself a result of product-line engineering. This paper describes how megaprogramming principles are being applied to assemble and integrate the SEE for one of the three STARS demonstration projects. It provides practical lesson learned, some hard-won, that should be useful to organizations planning their own SEE integration efforts, particularly for organizations considering a transition to megaprogramming. THE SOCIOLOGY OF MEGAPROGRAMMING: EXPERIENCES IN GENERATING AN ORGANIZATIONAL LEARNING ENTERPRISE (SOFTWARE TECHNOLOGY FOR ADAPTABLE, RELIABLE SYSTEMS(STARS) PROGRAM)
Lynn B. Underhill 27 Jan. 1995 35 p
(Contract F19628-93-C-0129)
(AD-A292998) Avail: CASI HC A03/MF A01

The STARS Program is currently involved in transitioning advanced software engineering technologies into practice within the DOD under the aegis of 'megaprogramming.' Megaprogramming, which integrates the notions of process-driven, domain specific, reuse based, and supporting automation via a software engineering environment, is intended to enable the formation of product-line organizations with the objective of producing systems 'cheaper, better, faster.' Transitioning to megaprogramming can involve significant changes to existing ways of doing business, and to an organization's underlying paradigms. Given the degree of change, sociological forces come into play. The project that forms the basis of this experience is the SCAT demonstration project, performed by the AF SWSC at Peterson AFB. As a vehicle for organizing the analysis of our project's experience, we will relate it to the disciplines distinguished by Peter Senge in 'The Fifth Discipline, the Art and Practice of the Learning Organization.' For each discipline, we present our interpretation of our experience, and our recommendations based on our lessons. DTIC

ANALYSIS OF THE FINAL RESULT FROM THE IMAGE TEMPLATE MATCHING METHOD WITH FUZZY LOGIC [ANALYS AV SLUTRESULTATET VID MODELLBASERAD BILDMATCHNING MED OSKARP LOGIK]
A. Malmros Aug. 1994 108 p In SWAHILI
(PB95-222915; FOA-R-94-00011-3.4-SE) Avail: Issuing Activity (National Technical Information Service (NTIS))

This report presents an algorithm used to mark the quality of an image template matching and a literature study concerning fuzzy logic and fuzzy sets. When using an image template matching method, for instance the Hierarchical Chamfer Matching Algorithm, the result is a list of measurements. The measurements describe, pixel by pixel, the distance between a point on the template and nearest edge from the original picture. The algorithm, called Malmros' algorithm, constructs fuzzy sets on the measurements using statistics and weights them using fuzzy logic. Finally, defuzzification is used to get a per cent value as a measurement of the quality of the image template matching. The algorithm has been tested on available material and no greater disadvantage of the method has been noticed. The algorithm gives a good, but not optimal, solution of the problem. NTIS

AN OVERVIEW OF HIGH-SPEED NETWORKING FOR WORKSTATIONS
K. Hake 1995 15 p Presented at the Geographic Information System (GIS), Vancouver, Canada, 27-30 Mar. 1995
(Contract DE-AC05-84OR-21400)
(DE95-009076; CONF-9503121-1) Avail: CASI HC A03/MF A01

The telecommunications industry provides new technologies for GIS (Geographic Information System) workstation upgrades: Fast Ethernet, 100VG-AnyLAN, and Asynchronous Transfer Mode (ATM). These network technologies are based on approved standards and have industry backing (alliance for Fast Ethernet). This paper briefly examines these technologies. Fast Ethernet is an extension to its predecessor 10 Mbps Ethernet, providing a 10x increase in transmission rate. 100VG-AnyLAN offers extensions to Ethernet but embraces the Token Ring technology, allowing internetworking and better performance for networked video. ATM takes a radial approach by simplifying the information quantum to a 53-byte cell, resulting in rapid data handling for telecommunications equipment and allowing efficient transport of data, video, and voice communications. Switched Ethernet and Full Duplexing are among the other technologies competing for this market. The ultimate test of usefulness for any technology lies in how they handle the GIS environment requirements; working demonstration systems will help clarify marketing rhetoric and determine which vendor best implemented the standard. RECOMMENDATIONS FOR DEVELOPING PORTABLE PARALLEL I/O FACILITIES FOR SCIENTIFIC APPLICATIONS
R. K. Yates 1 Dec. 1994 8 p
(Contract W-7405-eng-48)
(DE95-009384; UCRL-ID-119528) Avail: CASI HC A02/MF A01

We outline a plan to develop portable parallel I/O facilities for scientific applications on parallel computers. We recommend that efforts be focussed on three areas: a new standard I/O library for message passing environments, efficient parallel I/O implementations for data parallel programming in Fortran 90 and High Performance Fortran (which may require new parallel I/O commands), and the promotion of high performance parallel I/O facilities in high-level scientific toolkits. In the next year we will concentrate primarily on the first area, designing and implementing a portable parallel I/O library to work with the new MPI standard Message Passing Interface. DOE

WIDE AREA NETWORKING R&D Final Report, 3 Jan. 1989 - 3 May 1993
Richard Mandelbaum and James D. Luckatt Dec. 1994 134 p
(Contract F30602-89-C-0016; ARPA Order 6474; ARPA Order 6797)
(AD-A291057; NYSERNET-01; RL-TR-94-2113) Avail: CASI HC A07/MF A02

This was a joint Rome Laboratory/ARPA advanced development effort that: (1) provided wide area high speed networking services for the New York State (NYS) Arpanet; (2) created the National Networking Testbed (NNET); and (3) developed Simple Network Management Protocol (SNMP) software tools. Under the first task, existing NYS Arpanet users were provided Transmission Control Protocol/Internet Protocol (TCP/IP) network service and support, access to the Defense Research Internet (DRI) with connectivity to the Internet, and upgraded service from 56 kbps to 1.544 mbps. The second task involved the installation and operation of the NNT, a nationwide, high-speed computer data network dedicated to ARPA's use to support domestic military and NASA sites, with access provided to the U.S. Dept. of Energy. The NNT provided a non-production network environment to field test a variety of network infrastructure devices and management control software tools. The third task involved the development of network management software technology to operate and maintain reliable end-to-end NNT connectivity. In addition to SNMP software tools, some software development work involved applications related to the International Standards Organization Development Environment (ISODE) and X.500 Directory areas. ALGORITHMS FOR CATEGORIZING MULTIPROCESSOR COMMUNICATION UNDER INVALIDATE AND UPDATE-BASED COHERENCE PROTOCOLS
Ricardo Bianchini and Leonidas Kontothanassis Sep. 1994 24 p
(Contract N00014-92-J-1801; ARPA Order 8930)
(AD-A290022; TR-533) Avail: CASI HC A03/MF A01

In this paper, we present algorithms that characterize the main sources of communication generated by parallel applications under both invalidate and update based cache coherence protocols. The algorithms provide insight into the reference and sharing patterns of parallel programs and into the amount of useless traffic entailed by each coherence protocol. Under an invalidate based protocol, our algorithms classify the data traffic caused by the different types of cache misses. Under an update based protocol, our algorithms not only categorize the data traffic, but also classify update transactions with respect to the sharing patterns that caused them. Although our algorithms deal with numerous hardware features such as finite sized caches and coalescing write buffers, our categorization is widely applicable and can be easily simplified for use in less detailed environments. Our work extends previous categorizations of cache misses in write invalidate protocols, while introducing a new categorization of the coherence traffic in update based protocols. DTIC

CLIENT SERVER ARCHITECTURE FOR MULTIDATABASE ACCESS. INGRES SQL SERVER
M. Dixon Nov. 1994 29 p Prepared in cooperation with Leeds Metropolitan Univ., Leeds, England
(PB95-192852; RAL-94-118) Avail: Issuing Activity (National Technical Information Service (NTIS))

The interoperating of multiple database systems requires a client application which acts as a mediating agent for database server processes; these server processes must be accessed using network procedure calls. This report addresses the problems and associated design options that arise in constructing a dynamic Structured Query Language (SQL) server process for the Ingres Relational Database Management System. The Ingres SQL server has been constructed in C on a Unix platform and accessed across a SunOS network. It is intended that the narrative in this report together with the source code for both the SQL Server and the primitive Client would act as a starting template for a writer of application code that required dynamic SQL access to an Ingres database. The choice of a network protocol is discussed. NTIS

INTEGRATED HIGH PERFORMANCE DISTRIBUTED SYSTEM Final Technical Report, Aug. 1992 - Feb. 1994
Dec. 1994 52 p
(Contract F30602-92-C-0102)
(AD-A292821; BBN-7987; RL-TR-94-237) Avail: CASI HC A04/MF A01

The objective of the Integrated High Performance Distributed System (IHPDS) project is to design, implement, and demonstrate a distributed programming environment that will integrate and support very high bandwidth networks with heterogeneous computer architectures, including parallel and specialized processors, and that will support multiple programming models. The IHPDS project is developing the Photon distributed programming environment to meet the emerging needs of distributed application programmers. Photon provides an object-oriented programming model. This

provides users with a consistent view of all services while insulating the user from the implementation details of those services. This enforcement of modularity and the separation of policy and mechanism make the object model a powerful way to build large-scale, distributed applications. Photon is a distributed computing environment that supports distributed application development across heterogeneous machine architectures and programming languages. It is particularly targeted to support the needs of high performance applications. Photon not only supports applications whose components are located within a single local area network, but also supports applications whose components are widely dispersed geographically. DTIC

REQUIREMENTS FOR SECURITY SIGNALLING
Lyndon G. Pierson and Thomas D. Tarman Feb. 1995 8 p Presented at the ATM Forum Technical Committee Meeting, Denver, CO, 10 Apr. 1995
(Contract DE-AC04-94AL-85000)
(DE95-008714; SAND-95-0486C; CONF-9504139-3) Avail: CASI HC A02/MF A01

There has been some interest lately in the need for 'authenticated signalling', and the development of signalling specifications by the ATM Forum that support this need. The purpose of this contribution is to show that if authenticated signalling is required, then supporting signalling facilities for directory services (i.e. key management) are also required. Furthermore, this contribution identifies other security related mechanisms that may also benefit from ATM-level signalling accommodations. For each of these mechanisms outlined here, an overview of the signalling issues and a rough cut at the required fields for supporting Information Elements are provided. Finally, since each of these security mechanisms are specified by a number of different standards, issues pertaining to the selection of a particular security mechanism at connection setup time (i.e. specification of a required 'Security Quality of Service') are also discussed. DOE

IMPROVING DATA CONSISTENCY IN MOBILE COMPUTING USING ISOLATION-ONLY TRANSACTIONS
Qi Lu and M. Satyanarayanan Mar. 1995 10 p Presented at the 5th Workshop on Hot Topics in Operating Systems, Orcas Island, WA, 4-5 May 1995
(Contract F19628-93-C-0193)
(AD-A293110; CMU-CS-95-126) Avail: CASI HC A02/MF A01

Disconnected operation is an important technique for providing mobile access to shared data in distributed file systems. However, data inconsistency resulting from partitioned sharing remains a serious concern. This paper presents a new mechanism called isolation-only transaction (IOT) that uses serializability constraints to automatically detect read/write conflicts. The IOT consistency model provides a set of options for automatic and manual conflict resolution. In addition, application specific knowledge can be incorporated to detect and resolve conflicts. To preserve upward Unix compatibility, the IOT mechanism is provided as an optional file system facility and its flexible interfaces allow any existing Unix application to be executed as an IOT. This paper describes high level system design and implementation and concludes with related work and current status. DTIC

SCALABLE ATM ENCRYPTION
1995 19 p Presented at the Cray User Group Spring Conference, Denver, CO, 15 Mar. 1995
(Contract DE-AC04-94AL-85000)
(DE95-009868; SAND-95-0661C; CONF-9503129-1) Avail: CASI HC A03/MF A01

In order to provide needed security assurances for traffic carried in Asynchronous Transfer Mode (ATM) networks, methods of protecting the integrity and privacy of traffic must be employed. Cryptographic methods can be used to assure authenticity and privacy, but are hard to scale and the incorporation of these methods into computer networks can severely impact functionality, reliability, and performance. To study these trade-offs, a research prototype encryptor/decryptor is under development. This prototype is to demonstrate the viability of implementing certain encryption techniques in high speed networks by processing Asynchronous Transfer Mode (ATM) cells in a SONET OC-3 payload. This paper describes the objectives and design trade-offs intended to be investigated with the prototype. User requirements for high performance computing and communication have driven Sandia to do work in the areas of functionality, reliability, security, and performance of high speed communication networks. Adherence to standards (including emerging standards) achieves greater functionality of high speed computer networks by providing wide interoperability of applications, network hardware, and network software. DOE

N95-32146# Sandia National Labs., Albuquerque, NM.
A PROPOSED GENERIC AUTHENTICATION INFORMATION ELEMENT
Thomas D. Tarman 10 Apr. 1995 5 p Presented at the ATM Forum Technical Committee Meeting, Denver, CO, 10 Apr. 1995
(Contract DE-AC04-94AL-85000)
(DE95-009862; SAND-95-0665C; CONF-9504139-2) Avail: CASI HC A01/MF A01

This contribution describes a proposed information element that can convey authentication information within an ATM signaling message. The design of this information element provides a large amount of flexibility to the user because it does not specify a particular signature algorithm, and it does not specify which information elements must accompany the Authentication IE in a signaling message. This allows the user to implement authenticated signaling based on her site's security policies and performance requirements. DOE

ASSIST USER MANUAL
Sally C. Johnson and David P. Boerschlein Aug. 1995 103 p Sponsored by NASA, Washington
(RTOP 505-64-10-07)
(NASA-TM-4592; L-17407; NAS 1.15:4592) Avail: CASI HC A06/MF A02

Semi-Markov models can be used to analyze the reliability of virtually any fault-tolerant system. However, the process of delineating all the states and transitions in a complex system model can be devastatingly tedious and error prone. The Abstract Semi-Markov Specification Interface to the SURE Tool (ASSIST) computer program allows the user to describe the semi-Markov model in a high-level language. Instead of listing the individual model states, the user specifies the rules governing the behavior of the system, and these are used to generate the model automatically. A few statements in the abstract language can describe a very large, complex model. Because no assumptions are made about the system being modeled, ASSIST can be used to generate models describing the behavior of any system. The ASSIST program and its input language are described and illustrated by examples. Author

COMPACT LOCATION PROBLEMS WITH BUDGET AND COMMUNICATION CONSTRAINTS
S. O. Krumke, H. Noltemeier (Wuerzburg Univ., Germany.), S. S. Ravi, and M. V. Marathe 1995 24 p Presented at the 1st Annual International Computing and Combinatorics Conference, Xian, China, 24 Aug. 1995

(Contract W-7405-eng-36)
(DE95-010876; LA-UR-95-1293; CONF-9508113-1) Avail: CASI HC A03/MF A01

We consider the problem of placing a specified number p of facilities on the nodes of a given network with two nonnegative edge-weight functions so as to minimize the diameter of the placement with respect to the first distance function under diameter or sum-constraints with respect to the second weight function. Define an (alpha, beta)-approximation algorithm as a polynomial-time algorithm that produces a solution within alpha times the optimal function value, violating the constraint with respect to the second distance function by a factor of at most beta. We observe that in general obtaining an (alpha, beta)-approximation for any fixed alpha, beta greater than or equal to 1 is NP-hard for any of these problems. We present efficient approximation algorithms for the case when both edge-weight functions obey the triangle inequality. For the problem of minimizing the diameter under a diameter constraint with respect to the second weight-function, we provide a (2,2)-approximation algorithm. We also show that no polynomial time algorithm can provide an (alpha, 2 minus epsilon) or (2 - epsilon, beta) approximation for any fixed epsilon greater than 0 and alpha, beta greater than or equal to 1, unless P = NP. This result is proved to remain true, even if one fixes epsilon' greater than 0 and allows the algorithm to place only 2p/(absolute value of V)(sup 1/(6 - epsilon')) facilities. Our techniques can be extended to the case when either the objective or the constraint is of sum-type and also to handle additional weights on the nodes of the graph. Here our heuristics provide performance guarantees of (2 - 2/p, 2) and (2, 2 - 2/p) respectively. DOE

A HEURISTIC AND COMPLETE PLANNER FOR THE CLASSICAL MOVER'S PROBLEM
Yong K. Hwang and Pang C. Chen 1995 8 p Presented at the 1995 International Conference on Robotics and Automation, Nagoya, Japan, 21-27 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-008440; SAND-95-0242C; CONF-9505193-1) Avail: CASI HC A02/MF A01

We present a motion planner for the classical mover's problem in three dimensions that is both resolution-complete and efficient in that it has performance commensurate with task difficulty. It is based on the SANDROS search strategy, which uses a hierarchical, multi-resolution representation of the configuration space along with a generate-and-test paradigm for solution paths. This planner can control the trade-offs between the computation resource and algorithmic completeness/solution path quality, and thus can fully utilize the available computing power. It is useful for navigation of mobile robots, submarines and spacecraft, or part motion feasibility in assembly planning. DOE

LEARNING IN AN INTENTIONAL SYSTEM Final Report, 1 Aug. 1991 - 31 Jul. 1994
Lawerence Birnbaum and Gregg Collins Dec. 1994 27 p
(Grant AF-AFOSR-0341-91)
(AD-A291158; AFOSR-95-0087TR) Avail: CASI HC A03/MF A01

The goal of the project, as outlined in the original proposal, was to carry out research aimed at the construction of adaptive planning systems that can learn in response to planning failures, i.e., modeling learning to plan as a process of debugging. Previous approaches to failure-driven learning have been based on a traditional models of planning, in which the planner generates a monolithic, self-contained plan to be passed on to another module for execution. Such approaches have thus focused on the process of debugging a plan that has proven to be faulty during execution. However, such traditional models of planning have increasingly come under attack, as it has come to be recognized that planners operating in the real world must be reactive, changing plans on the fly to cope with unexpected circumstances. In such a model, there may be no single, monolithic plan that governs the systems behavior during execution. DTIC

In this paper we study a single-server system with Erlang-r distributed service times and arbitrarily distributed interarrival times. It is shown that the waiting-time distribution can be expressed as a finite sum of exponentials, the exponents of which are the roots of an equation. Under certain conditions for the interarrival-time distribution, this equation can be transformed to r contraction equations, the roots which can be easily found by successive substitutions. The conditions are satisfied for several practically relevant arrival processes. The resulting numerical procedures are easy to implement and efficient and appear to be remarkably stable, even for extreme high value of r and for values of the traffic load close to 1. Numerical results are presented. NTIS

SELECTING OPTIMAL EXPERIMENTS FOR FEEDFORWARD MULTILAYER PERCEPTRONS Ph.D. Thesis
Lisa M. Belue Mar. 1995 187 p
(AD-A290856; AFIT/DS/ENS/95-01) Avail: CASI HC A09/MF A02

Where should a researcher conduct experiments to provide training data for a multilayer perceptron? This question is investigated and a statistically-based method for optimally selecting experimental design points for multilayer perceptrons is introduced. Specifically, a criterion is developed based on the size of an estimated confidence ellipsoid for the weights in the multilayer perceptron. This criterion is minimized over a set of exemplars to find optimal design points. Initially, single output networks are examined. An example is used to demonstrate the superiority of optimally selected design points over randomly chosen points and points chosen in a grid pattern. Also, two measures are successfully used to rank the design points in terms of their importance. Two methods are presented to significantly reduce complexity-a distributed linear feedthrough network structure and a weight subset method. Next, multiple output networks are examined. The criterion in this framework becomes more complex and a simplifying technique is employed to judiciously choose desired outputs of the network to produce uncorrelated actual outputs. Finally, the methods described above are integrated and tested on two applications dealing with aircraft survivability. In both cases, simulating the indicated experiments produced a superior multilayer perceptron. DTIC

ADAPTIVE PATH PLANNING: ALGORITHM AND ANALYSIS
Pang C. Chen 1995 8 p Presented at the 1995 International Conference on Robotics and Automation, Nagoya, Japan, 21-27 May 1995
(Contract DE-AC04-94AL-85000)
(DE95-008549; SAND-95-0241C; CONF-9505193-3) Avail: CASI HC A02/MF A01

To address the need for a fast path planner, we present a learning algorithm that improves path planning by using past experience to enhance future performance. The algorithm relies on an existing path planner to provide solutions to difficult tasks. From these solutions, an evolving sparse network of useful robot configurations is learned to support faster planning. More generally, the algorithm provides a framework in which a slow but effective planner may be improved both cost-wise and capability-wise by a faster but less effective planner coupled with experience. We analyze the algorithm by formalizing the concept of improvability and deriving conditions under which a planner can be improved within the framework. The analysis is based on two stochastic models, one pessimistic (on task complexity), the other randomized (on experience utility). Using these models, we derive quantitative bounds to predict the learning behavior. We use these estimation tools to characterize the situations in which the algorithm is useful and to provide bounds on the training time. In particular, we show how to predict the maximum achievable speedup. Additionally, our analysis techniques are elementary and should be useful for studying other types of probabilistic learning as well. DOE

FIXED MODES IN QUASI-STATIC STATE FEEDBACK DECOUPLING
R. Andiarti, C. H. Moog, and H. J. C. Huijberts Sep. 1994 15 p Prepared in cooperation with Nantes Univ.
(PB95-206850; MEMO-COSOR-94-30) Avail: CASI HC A03/MF A01

We consider the problem of noninteracting control with stability for a square affine nonlinear system, where its decoupling matrix is not necessarily invertible. The recent notion of quasi-static state feedback is used. The results of this paper show that the dimension of the fixed dynamics with respect to any quasi-static state feedback may be determined by using the so-called accessibility cospaces. NTIS

COMPUTERIZED DESIGN OF CONTROLLERS USING DATA MODELS Final Report
Dennis Irwin, Jerrel Mitchell, Enrique Medina, Dan Allwine, Garth Frazier, and Mark Duncan Jul. 1995 242 p
(Grant NAG8-217)
(NASA-CR-198921; NAS 1.26:198921) Avail: CASI HC A11/MF A03

The major contributions of the grant effort have been the enhancement of the Compensator Improvement Program (CIP), which resulted in the Ohio University CIP (OUCIP) package, and the development of the Model and Data-Oriented Computer Aided Design System (MADCADS). Incorporation of direct z-domain designs into CIP was tested and determined to be numerically ill-conditioned for the type of lightly damped problems for which the development was intended. Therefore, it was decided to pursue the development of z-plane designs in the w-plane, and to make this conversion transparent to the user. The analytical development needed for this feature, as well as that needed for including compensator damping ratios and DC gain specifications, closed loop stability requirements, and closed loop disturbance rejection specifications into OUCIP are all contained in Section 3. OUCIP was successfully tested with several example systems to verify proper operation of existing and new features. The extension of the CIP philosophy and algorithmic approach to handle modern multivariable controller design criteria was implemented and tested. Several new algorithms for implementing the search approach to modern multivariable control system design were developed and tested. This analytical development, most of which was incorporated into the MADCADS software package, is described in Section 4, which also includes results of the application of MADCADS to the MSFC ACES facility and the Hubble Space Telescope. APPLICATION OF GENETIC ALGORITHMS AND MACHINE LEARNING TO SCHEDULING Final Report
Sherif M. Botros and Alper K. Caglayan 14 Jun. 1995 41 p
(Contract NAS9-19263)
(NASA-CR-198965; R94281; NAS 1.26:198965) Avail: CASI HC A03/MF A01

While there exists a number of successful heuristic scheduling rules, these rules usually suffer from limited applicability and unpredicted performance. The main objective of this Phase 1 effort is to demonstrate the feasibility of applying the emerging optimization and machine learning technology in scheduling. The incorporation of machine learning capability in scheduling provides generality and wide applicability in addition to improved schedule quality. In Phase 1, we explored the application of recurrent neural networks, genetic algorithms (GA) and reinforcement learning (RL) to resource constrained scheduling and tested their feasibility in realistic scheduling problems. The specific tasks performed during the Phase 1 effort are: (1) the specification and design of a machine-learning-based intelligent scheduler which combines scheduling heuristic rules and machine learning techniques to improve scheduling performance; (2) testing the feasibility of applying GA and RL techniques to scheduling, and demonstrating how these techniques result in good performance when applied to realistic complex scheduling problems; (3) implementing many of the supporting scheduling tools in the form of C++ class libraries; and (4) specifying the requirements for a Phase 2 full-scope implementation. The results obtained in Phase 1 demonstrate the feasibility and advantages of developing a machine-learning-based scheduler. Author

GENERALIZED CONTROLLED INVARIANCE FOR NONLINEAR SYSTEMS
H. J. C. Huijberts, C. H. Moog, and R. Andiarti Nov. 1994 35 p
(PB95-197901; MEMO-COSOR-94-34) Avail: CASI HC A03/MF A01

A general setting is developed which describes controlled invariance for nonlinear control systems and which incorporates the previous approaches dealing with controlled invariant (co-) distributions. A special class of controlled invariant subspaces, called controllability cospaces, is introduced. These geometric notions are shown to be useful for deriving a (geometric) solution to the dynamic disturbance decoupling problem and for characterizing the so-called fixed dynamics for the general input-ouput noninteracting control problem via dynamic compensation. These fixed dynamics are a major issue for studying noninteracting control with stability. The class of quasi-static state feedbacks is used. NTIS

NOISY-NETWORK ACCEPTORS
M. F. J. Drossaers Oct. 1994 119 p
(PB95-197976; Memo-INF-94-63) Copyright Avail: CASI HC A06/MF A02

In this paper a number of neural networks for sequence recognition is reviewed, and a noisy version of the neural-network acceptor, the noisy-network acceptor, is introduced and analyzed. The paper starts off exposing the computational weakness of attractor neural networks in sequence recognition tasks. This shows very explicitly to what problem the neural-network acceptor provides an answer. The theory of noisy-network acceptors introduced in this paper provides a framework for the examination of sequence recognition if the acceptor is subjected to noise. Analyses of the noisy-network acceptor's performance show that the noisy-network acceptor is a robust recognition device. Also a great agreement between analytical and simulation results was found. H(SUB 2) OPTIMAL CONTROLLERS WITH OBSERVER BASED ARCHITECTURE FOR CONTINUOUS-TIME SYSTEMS: SEPARATION PRINCIPLE
Ali Saberi, Peddapullaiah Sannuti, and A. A. Stoorvogel 9 Dec. 1994 30 p Prepared in cooperation with Washington State Univ., Pullman and Rutgers State Univ., Piscataway, NJ
(PB95-197067; MEMO-COSOR-94-41) Avail: CASI HC A03/MF A01

For a general H(sub 2) optimal control problem, at first all H(sub 2) optimal measurement feedback controllers are characterized and parameterized, and then attention is focused on controllers with observer based architecture. Both full order as well as reduced order observer based H(sub 2) optimal controllers are characterized and parameterized. Also, systematic methods of designing them are presented. An important problem that can be coined as an H(sub 2) optimal control problem with simultaneous pole placement, is formulated and solved. That is, since in general there exist many H(sub 2) optimal measurement feedback controllers, utilizing such flexibility and freedom, we can solve the problem of simultaneously placing the closed-loop poles at desirable locations whenever possible while still preserving H(sub 2) optimality. All the design algorithms developed here are easily computer implementable. NTIS

NEURODYNAMICAL SYSTEMS FOR COGNITION AND TARGET IDENTIFICATION Final Technical Report, 1 Jul. 1991 - 30 Jun. 1994
N. H. Farhat Oct. 1994 83 p
(Contract DAAL03-91-G-0209)
(AD-A293111; ARO-28125.9-MA) Avail: CASI HC A05/MF A01

Our study of cognitive automated target recognition (ATR) based on the neural paradigm for information processing reveals that inclusion of bifurcation and synchronicity (phase-locking) in network dynamics can markedly improve the performance of ATR systems. This gave impetus to our study of how synchronicity could arise in cortical networks when it is known the brain has no central clock. Raising this question has led us, through analysis of models of biological neurons employing the tools of nonlinear dynamics, to the development of the bifurcating neuron concept and model. This spiking neuron model combines functional complexity comparable to that of biological neurons with structural simplicity and low power consumption when implemented electronically or optoelectronically. These attributes make the bifurcating neuron ideally suited for use as building block of a new generation of spiking neural networks that employ phase-locking, bifurcation, and chaos, on the single processing element level, to emulate higher-level cortical functions such as feature-binding and cognition that are essential for advanced ATR systems, and other operations like separation of object from background, inferencing, and rudimentary reasoning. Given the exponential growth in the number of images stored in databases around the world, there is a clear need for computer-assisted means of searching images. Keywords and computed indices, referred to as metadata, can be used to tag images for subsequent retrieval. Most potential applications, however, will require searching for images on the basis of image content, but existing techniques for content-based search are either too slow, customized at great expense for a single application, or simply do not work well. An environment has been created enabling a user with limited computer skills to interactively train a computer algorithm to recognize patterns of spectral or textural features in imagery. The trained algorithm can then be exported as an independent agent to search large databases for matching image patterns. Following their retrieval, a user can further refine agent performance by indicating mistakes. The final product is a search tool capable of prescreening and highlighting images, significantly reducing the workload of analysts attempting to detect regions or objects in imagery. An approach to interactive learning has been developed as part of this environment. Based on techniques of knowledge-based image processing, this approach uses interest images to provide a means of continuous feedback of algorithm performance to the user, who in turn responds by indicating where the algorithm is making mistakes. The set of user-indicated examples and counterexamples form the inputs to a new machine learning algorithm called functional template learning. This algorithm is competitive with other machine learning techniques in terms of classification accuracy and exhibits several advantages in terms of speed and understandability that make it particularly well suited to interactive, supervised machine learning and autonomous searching of databases. MAKING INTELLIGENT SYSTEMS TEAM PLAYERS. A GUIDE TO DEVELOPING INTELLIGENT MONITORING SYSTEMS
Sherry A. Land, Jane T. Malin, Carroll Thronesberry (Metrica, Inc., Houston, TX.), and Debra L. Schreckenghost (Metrica, Inc., Houston, TX.) Jul. 1995 100 p
(NASA-TM-104807; S-790; NAS 1.15:104807) Avail: CASI HC A05/MF A02

This reference guide for developers of intelligent monitoring systems is based on lessons learned by developers of the DEcision Support SYstem (DESSY), an expert system that monitors Space Shuttle telemetry data in real time. DESSY makes inferences about commands, state transitions, and simple failures. It performs failure detection rather than in-depth failure diagnostics. A listing of rules from DESSY and cue cards from DESSY subsystems are included to give the development community a better understanding of the selected model system. The G-2 programming tool used in developing DESSY provides an object-oriented, rule-based environment, but many of the principles in use here can be applied to any type of monitoring intelligent system. The step-by-step instructions and examples given for each stage of development are in G-2, but can be used with other development tools. This guide first defines the authors' concept of real-time monitoring systems, then tells prospective developers how to determine system requirements, how to build the system through a combined design/development process, and how to solve problems involved

in working with real-time data. It explains the relationships among operational prototyping, software evolution, and the user interface. It also explains methods of testing, verification, and validation. It includes suggestions for preparing reference documentation and training users. Author

A TWO-TIMESCALE APPROACH TO NONLINEAR MODEL PREDICTIVE CONTROL
Kevin L. Buescher and Christopher C. Baum 1994 18 p Presented at the 1995 American Control Conference, Seattle, WA, Jun. 1995
(Contract W-7405-eng-36)
(DE95-000943; LA-UR-94-3256; CONF-950653-1) Avail: CASI HC A03/MF A01

Model predictive control (MPC) schemes generate controls by using a model to predict the plant's response to various control strategies. A problem arises when the underlying model is obtained by fitting a general nonlinear function, such as a neural network, to data: an exorbitant amount of data may be required to obtain accurate enough predictions. We describe a means of avoiding this problem that involves a simplified plant model which bases its predictions on averages of past control inputs. This model operates on a timescale slower than the rate at which the controls are updated and the plant outputs are sampled. Not only does this technique give better closed-loop performance from the same amount of open-loop data, but it requires far less on-line computation as well. We illustrate the usefulness of this two-timescale approach by applying it to a simulated exothermic continuously stirred tank reactor with jacket dynamics. DOE

HIGH-TECH CONTROLS FOR ENERGY AND ENVIRONMENT
S. J. Biondo, ed. and C. J. Drummond, ed. 1994 287 p Presented at the Adaptive Control Systems Technology Symposium, Pittsburgh, PA, 24-25 Oct. 1994
(DE95-011702; CONF-9410335) Avail: CASI HC A13/MF A03

The Department of Energy, in cooperation with the IEEE Neural Networks Council, Naval Research Laboratory, Electric Power Research Institute, and U.S. Bureau of Mines, sponsored the Adaptive Control Systems Technology Symposium in Pittsburgh, Pennsylvania from October 24 to 25, 1994. The theme of the Symposium was High-Tech Controls for Energy and Environment. This extraordinary gathering was designed to bring together individuals from the control systems and computational intelligence communities to focus attention on potential benefits to be derived from the application of adaptive controls to energy and environmental systems. Leading authorities from industry, academic, and government institutions presented tutorial overviews on each of three computational intelligence paradigms -- viz., neural networks, fuzzy logic, genetic algorithms -- identified useful hybrid forms, and introduced intelligent and adaptive control systems concepts and applications. There were also papers presented that focussed on specific applications of intelligent control and adaptive control in energy and environmental control systems. Individual papers have been cataloged separately. DOE

ACQUIRING CONSISTENT KNOWLEDGE FOR BAYESIAN FORESTS M.S. Thesis
Darwyn O. Banks Mar. 1995 101 p
(AD-A293858; AFIT/GSO/ENG/95M-01) Avail: CASI HC A06/MF A02

This thesis develops a methodology and a tool for knowledge acquisition with the new probabilistic knowledge representation-the Bayesian Forest. It establishes the structure of the Knowledge Acquisition and Maintenance module of the Probabilities, Expert Systems, Knowledge and Inference (PESKI) architecture. The tool, MACK, is designed to be used directly by the domain expert(s) rather than by knowledge engineer(s), and thus supports automated knowledge acquisition. This research determines and implements the constraints necessary to ensure the consistency of Bayesian Forest knowledge bases as data is both acquired and subsequently maintained. The impact to the PESKI architecture of time-dependent information and default assumptions during reasoning is also explored. The tool has been applied to NASA's Post-Test Diagnostics System which locates anomalies aboard the Space Shuttles' Main Engines. DTIC

NEURAL NETWORK FALSE ALARM FILTER, VOLUME 1 Report, Sep. 1992 - 1994
F. Ayistock, L. Elerin, J. Hintz, C. Learoyd, and R. Press Dec. 1994 186 p
(AD-A293097; RL-TR-94-216) Avail: CASI HC A09/MF A02

This effort identified, developed and demonstrated a set of approaches for applying neural network learning techniques to the development of a real-time built-in test (BIT) capability to filter out false-alarms from the BIT output. Following a state-of-the-art assessment, a decision space of 19 neural network models, 9 fault report causes and 12 common groups of BIT techniques was identified. From this space, 4 unique, high-potential combinations were selected for further investigation. These techniques were subsequently simulated for application to a MILSATCOM system. Detailed analyses of their strengths and weaknesses were performed along with cost/benefit analyses. This study concluded that the best candidates for neural network insertion are new systems where neural network requirements can be included in the initial system design and that a major challenge is the availability or real data for training of the networks. Volume 1 of this report documents the activities and findings of the effort, including an extensive, annotated bibliography. Volume 2 contains a tutorial overview of the neural networks, BIT techniques and false alarm causes utilized in the final phases of this study. DTIC

THE EFFECT OF REPEATEDLY SAMPLING AN EMBEDDED METAMODEL ON THE SIMULATION RESPONSE M.S. Thesis
J. K. Patterson Mar. 1995 49 p
(AD-A293783; AFIT/GOA/ENS/95M-6) Avail: CASI HC A03/MF A01

This study investigated the effect on simulation output of repeatedly sampling an embedded metamodel. A metamodel is said to be embedded within a simulation if it is used to replace a submodule of that simulation. Replacing a deterministic module with an embedded deterministic metamodel poses no apparent mathematical problems. However, using a deterministic metamodel to replace a stochastic simulation component could require additional corrective actions. This research was performed in two phases. The first phase dealt with a set of tandem queues. It was shown that as each queue was sequentially replaced with a metamodel, the total system variance was inappropriately diminished. A theoretical model of the error components was postulated and used to compensate for this missing variation, restoring the parent simulation's variance to approximately its original level. In the second phase, the problem was extended to the case of repeatedly sampling an embedded metamodel with similar results. In addition, guidelines for metamodel use were presented. In some situations, sampling from a probability distribution is more appropriate than the use of metamodel. DTIC

USING CASE-BASED REASONING AS A REINFORCEMENT LEARNING FRAMEWORK FOR OPTIMIZATION WITH CHANGING CRITERIA
Dajun Zeng and Katia Sycara Mar. 1995 17 p
(Contract F30602-91-C-0016)
(AD-A293602; CMU-RI-TR-95-13) Avail: CASI HC A03/MF A01

Practical optimization problems such as job-shop scheduling of-ten involve optimization criteria that change over time. Repair-based frameworks have been identified as flexible computational paradigms for difficult combinatorial optimization problems. Since the control problem of repair-based optimization is severe, Reinforcement Learning (RL) techniques can be potentially helpful. However, some of the fundamental assumptions made by traditional RL algorithms are not valid for repair-based optimization. Case-Based Reasoning (CBR) compensates for some of the limitations of traditional RL approaches. In this paper, we present a Case-Based Reasoning RL approach, implemented in the CABINS system, for repair-based optimization. We chose job-shop scheduling as the testbed for our approach. Our experimental results show that CABINS is able to effectively solve problems with changing optimization criteria which are not known to the system and only exist implicitly in a extensional manner in the case base. NEURAL NETWORK BASED DATA FUSION SYSTEM Patent Application
Chris DeAngelis, inventor (to Navy) and Robert Green, inventor (to Navy) 18 Oct. 1994 30 p
(AD-D017440; US-Patent-Appl-SN-324641) Avail: CASI HC A03/MF A01

A method is described for providing an estimate of the state of a moving contact. The method comprises providing a device for estimating the state of the contact; inputting information about a location of an observer platform at particular time intervals and information from at least one sensor about a position of the moving contact relative to the observer platform at each time interval into the device; transforming the inputted information into a series of geographical grids with one grid being formed for each reading of the at least one sensor; combining grids corresponding to similar time intervals into a series of consolidated grid representations; and analyzing the series of consolidated grid representations to produce an estimate of the state of the contact at a final point in time where an observation was made. The device of the present invention includes a grid stimulation block for forming the geographical grids, a fusion block for forming the consolidated grid representations, a correlation block for providing a path likelihood vector, and an estimation block for providing the desired estimate. NEURAL NETWORK BASED THREE DIMENSIONAL OCEAN MODELER Patent Application
Chris M. DeAngelis, inventor (to Navy) 11 Oct. 1994 26 p
(AD-D017441; US-Patent-Appl-SN-324640) Avail: CASI HC A03/MF A01

A method is described for providing an estimate of the state of a moving contact in a three dimensional ocean. The method comprises the steps of providing a device for estimating the state of the contact, inputting into the device information about a location of an observer during a sequence of time, information from at least one sensor about a position of the contact relative to the observer during the time sequence, and a knowledge vector, transforming the inputted information into a series of three dimensional geographical grids, and analyzing the geographical grids to produce an estimate of the state of the contact with respect to the location of the observer. The device for providing the estimate of the state of the moving contact is a neurally inspired contact estimation device. The device includes a grid stimulation block for transforming the inputted information into the three dimensional geographical grids, a fusion block where grids corresponding to similar time intervals are combined or fused, a correlation block for providing constraints such as constant speed and heading and for producing a path likelihood vector, and an estimation block for providing the estimate of the state of the moving contact. The device further includes a controller for providing knowledge to the aforementioned blocks. DTIC

PRODUCTION MATCHING FOR LARGE LEARNING SYSTEMS Ph.D. Thesis
Robert B. Doorenbos 31 Jan. 1995 208 p Sponsored by the National Science Foundation, Wright Lab., Aeronautical Systems Center, Air Force Materiel Command, USAF, and the Advanced Research Projects Agency
(Contract F33615-98-1-1330)
(AD-A293105; CMU-CS-95-113) Avail: CASI HC A10/MF A03

One of the central results of AI research in the 1970's was that to

achieve good performance, AI systems must have large amounts of knowledge. Machine learning techniques have been developed to automatically acquire knowledge, often in the form of if-then rules (productions). Unfortunately, this often leads to a utility problem - the 'learning' ends up causing an overall slowdown in the system. This is because the more rules a system has, the longer it takes to match them against the current situation in order to determine which ones are applicable. To address this problem, this thesis is aimed at enabling the scaling up of the number of rules in production systems. We examine a diverse set of testbed systems, each of which learns at least 100,000 rules. We show that with the best existing match algorithms, the match cost increases linearly in the number of rules in these systems. This is inadequate for large learning systems, because it leads to a utility problem. We then examine the causes of this linear increase, and develop techniques which eliminate the major causes. The end result is an improved match algorithm, Rete/UL, which is a general extension of the existing state-of-the-art Rete match algorithm. Rete/UL's performance scales well on a significantly broader class of systems than existing match algorithms. The use of Rete/UL rather than Rete significantly reduces or eliminates the utility problem in all the testbed systems. DTIC

ARTIFICIAL NEURAL NETWORKS AND MODEL-BASED RECOGNITION OF 3-D OBJECTS FROM 2-D IMAGES Ph.D. Thesis
Chih-ho Chao 1994 190 p
Avail: Univ. Microfilms Order No. DA9424550

A computer vision system is developed for 3-D object recognition from a 2-D gray-scale image with the application of artificial neural networks in both low-level and high-level process and with the usage of a model-based top-down feedback analysis approach. This vision system can adequately address the problems caused by using an incomplete edge map which is provided by the low-level processor for 3-D representation and recognition. This system uses the key patterns which are assigned with priorities by the intermediate-level organizer. The highest priority is given to a key pattern with the most connected node and associated features including the space invariant structure and the information of orientation of edge primitives. The labeled key features are mapped to real space and provided as input to an artificial neural network for the purpose of matching. Hopfield-Tank neural networks have been applied to low-level edge detection and to high-level matching. In the intermediate level, the edges extracted by the low-level processor are reprocessed and organized into various edge key patterns with priorities assigned. The features of the connected edge primitives are mapped to computable real numbers. A candidate with the highest priority is selected and sent to the high level for matching through the model base. The first match is to choose the class of possible model, the second match is to find the model closest to the candidate. In the end, the closest model is rotated in 3-D space to achieve the best match with the candidate. The result of such match is utilized in generating the model-driven top-down feedback analysis to verify the recognition and to provide the inherent 3-D features of objects. In the case of multiple objects, this matching strategy is very active and powerful in its ability to recognize objects using one pattern at a time. It is also suitable to recognize partially occluded objects. Dissert. Abstr.

STABILITY ANALYSIS OF LINEAR CONTROL SYSTEMS WITH UNCERTAIN PARAMETERS Ph.D. Thesis
Yuguang Fang 1994 326 p
Avail: Univ. Microfilms Order No. DA9425520

In this dissertation, we study stochastic stability of linear systems whose parameters are randomly varying in a certain sense. In particular, we present a new approach to stochastic stability analysis of systems whose system structure is randomly changing among a finite set of possibilities which capture the abrupt changes in systems parameters or sudden failures of system components. These types of systems are referred to as jump linear systems with a finite state Markov chain form process. We first investigate the properties of various types of moment stability for stochastic jump linear systems, and use large deviation theory to study the relationship between 'lower moment' stability and almost sure stability. In particular, we have proved that the region for delta-moment stability is monotonically increasing as delta is decreasing to zero and asymptotically converges to the region for almost sure stability. Roughly speaking, this is equivalent to saying that almost sure stability is equivalent to delta-moment stability for sufficiently small delta greater than 0. Furthermore, we prove that although the top delta-moment Lyapunov exponent is, in general, not differentiable at zero, it is differentiable at zero from the right and its right derivative at zero is equal to the top Lyapunov exponent. This answers a long standing question in this area. Based on this analysis, a new Lyapunov function is constructed to obtain a very general sufficient condition for almost sure stability, and this condition is also conjectured to be a necessary condition for almost sure stability. Moreover, a few new approaches for the study of almost sure stability are proposed and some easily-testable conditions for both moment stability and almost sure stability are obtained. Based on the results on almost sure stability and moment stability, the stochastic stabilization problem is also considered and a few future research topics are identified. This dissertation is the first research work in the current literature to use large deviation theory to study stochastic stability and further represents a systematic study of almost sure stability of jump linear systems with a finite state Markov chain form process. It is our high hope that this work will pave the way for further studies on the almost sure (sample path) stability for stochastic systems. Dissert. Abstr.

MULTIDIMENSIONAL DISCRETIZATION OF CONSERVATION LAWS FOR UNSTRUCTURED POLYHEDRAL GRIDS
D. E. Burton 22 Aug. 1994 26 p Presented at the SAMGOP-1994: 2d International Workshop on Analytical Methods and Process Optimization in Fluid and Gas Mechanics, Arzamas, Russia, 10-16 Sep. 1994 Submitted for publication
(Contract W-7405-eng-48)
(DE95-008796; UCRL-JC-118306; CONF-9409314-1) Avail: CASI HC A03/MF A01

To the extent possible, a discretized system should satisfy the same conservation laws as the physical system. The author considers the conservation properties of a staggered-grid Lagrange formulation of the hydrodynamics equations (SGH) which is an extension of a 1D scheme due to von Neumann and Richtmyer (VNR). The term staggered refers to spatial centering in which position, velocity, and kinetic energy are centered at nodes, while density, pressure, and internal energy are at cell centers. Traditional SGH formulations consider mass, volume, and momentum conservation, but tend to ignore conservation of total energy, conservation of angular momentum, and requirements for thermodynamic reversibility. The author shows that, once the mass and momentum discretizations have been specified, discretization for other quantities are dictated by the conservation laws and cannot be independently defined. The spatial discretization method employs a finite volume procedure that replaces differential operators with surface integrals. The method is appropriate for multidimensional formulations (1D, 2D, 3D) on unstructured grids formed from polygonal (2D) or polyhedral (3D) cells. Conservation equations can then be expressed in conservation form in which conserved currents are exchanged between control volumes. In addition to the surface integrals, the conservation equations include source terms derived from physical sources or geometrical considerations. In Cartesian geometry, mass and momentum are conserved identically. Discussion of volume conservation will be temporarily deferred. The author shows that the momentum equation leads to a form-preserving definition for kinetic energy and to an exactly conservative evolution equation for internal energy. Similarly, the author derives a form-preserving definition and corresponding conservation equation for a zone-centered angular momentum. DOE

THREE-D MESH OPTIMIZATION METHODS FOR UNSTRUCTURED POLYHEDRA Progress Report
Douglas S. Miller and Donald E. Burton 22 Nov. 1994 6 p Presented at the Nuclear Explosives Code Developers Conference (NECDC), Las Vegas, NV, 25-28 Oct. 1994 Submitted for publication
(Contract W-7405-eng-48)
(DE95-008808; UCRL-JC-119206; CONF-9410254-5) Avail: CASI HC A02/MF A01

A mesh optimization scheme allows a Lagrangian code to run problems with extreme mesh distortion by reconfiguring node and zone connectivity as the problem evolves. We have developed some 3D mesh optimization operations and criteria for applying them. These are demonstrated in a 3D Free Lagrange code being developed at LLNL. In the simplest case of a mesh or mesh subregion composed purely of tetrahedra we can maintain a Delaunay tetrahedralization. For more interesting meshes, made up of general polyhedra, a suite of optimization operations and their respective application criteria have been developed. DOE

CANONICAL SYMMETRIC INVARIANT PAIRINGS IN VERTEX OPERATOR SUPER ALGEBRAS AND GRAMIANS
H. Tamanoi Feb. 1995 49 p
(PB95-208112; IHES/M/95/14) Avail: CASI HC A03/MF A01

Any connected vertex operator super algebra canonically admits a symmetric bilinear pairing with various operator invariance properties including the translation invariance. The notion of quasi-primary vectors lead to an orthogonal double grading of the algebra. The canonical Hermitian pairings associated to certain conjugate linear involutions are shown to be positive definite and integral for algebras generated by vectors of weight one half. No Hilbert space structure is assumed. We deduce it. Our construction can be carried out over the ring of integers. The canonical pairings of basis vectors can be expressed in terms of the Gramian determinants of matrices of binomial coefficients. The proof of positive definiteness of the Hermitian pairings uses the integral representation of the Gramian determinants. NTIS

LOCAL INDEX FORMULA IN NONCOMMUTATIVE GEOMETRY
A. Connes and H. Moscovici Mar. 1995 86 p
(PB95-208146; IHES/M/95/19) Avail: CASI HC A05/MF A01

In noncommutative geometry, a geometric space is described from a spectral point of view, as a triple (A, H, D) consisting of a *-algebra A represented in a Hilbert space H together with an unbounded self-adjoint operator D, with compact resolvent, which interacts with the algebra in a bounded fashion. This paper contributes to the advancement of this point of view in two significant ways: (1) by showing that any pseudogroup of transformations of a manifold gives rise to such a spectral triple of finite summability degree, and (2) by proving a general, in some sense universal, local index formula for an arbitrary spectral triple of finite summability degree, in terms of the Dixmier trace and its residue-type extension. NEWTON METHODS FOR LARGE-SCALE LINEAR INEQUALITY-CONSTRAINED MINIMIZATION: OPTIMIZATION AND SYSTEMS THEORY
A. Forsgren and W. Murray Dec. 1994 20 p
(PB95-210332; TRITA-MAT-1994-44) Copyright Avail: CASI HC A03/MF A01

Newton methods of the linesearch type for large-scale minimization subject to linear inequality constraints are discussed. The purpose of the paper is twofold: (1) to give an active-set type method with the ability to delete multiple constraints simultaneously and (2) to give a relatively short general convergence proof for such a method. It is also discussed how multiple constraints can be added simultaneously. The approach is an extension of previous work by the same authors for equality-constrained problems. It is shown how the search directions can be computed without the need to compute the reduced Hessian of the objective function. The convergence analysis states that every limit point of a sequence of iterates satisfies the second-order necessary optimality conditions. NTIS

GIBBS MEASURES AND QUASI-PERIODIC SOLUTIONS FOR NONLINEAR HAMILTONIAN PARTIAL DIFFERENTIAL EQUATIONS
J. Bourgain Feb. 1995 21 p
(PB95-207932; IHES/M/95/13) Avail: CASI HC A03/MF A01

The purpose of this expose is to present a summary of some new developments in the theory of Hamiltonian nonlinear evolution equations, more specifically, nonlinear Schrodinger equations. The themes and methods discussed are closely related to classical mechanics. The first topic is the existence of an invariant measure for the flow. This invariant measure is the (properly normalized) Gibbs measure from statistical mechanics and we establish wellposedness of the equation on its support. Results are obtained in 1D (in the focusing and defocusing case) and in the 2D defocusing case. The second topic concerns the persistency of time periodic and quasi-periodic solutions for Hamiltonian perturbations of linear and integrable equations. We follow a method, the so-called Liapounov-Schmidt decomposition. The main advantage of this technique is the fact that it overcomes certain limitations of the KAM scheme, which is necessary to deal in particular with the problems in space-dimension D = or greater than 2. This work is a new approach to KAM problems, also in finite dimensional phase space. NTIS

(PB95-208039; RAL-95-009) Avail: Issuing Activity (National Technical Information Service (NTIS))

We consider the global and local convergence properties of a class of augmented Lagrangian methods for solving nonlinear programming problems. In these methods, linear and more general constraints are handled in different ways. The general constraints are combined with the objective function in an augmented Lagrangian. The iteration consists of solving a sequence of subproblems; in each subproblem the augmented Lagrangian is approximately minimized in the region defined by the linear constraints. A subproblem is terminated as soon as a stopping condition is satisfied. The stopping rules that we consider here encompass practical tests used in several existing packages for linearly constrained optimization. Our algorithm also allows different penalty parameters to be associated with disjoint subsets of the general constraints. In this paper, we analyze the convergence of the sequence of iterates generated by such an algorithm and prove global and fast linear convergence as well as showing that potentially troublesome penalty parameters remain bounded away from zero. GENERALIZED KUMMER SURFACES AND DIFFERENTIABLE INVARIANTS OF NOETHER-HORIKAWA SURFACES 1
Fabrizio Catanese Nov. 1994 55 p
(DE95-613382; IC-94/341) Avail: CASI HC A04/MF A01 (US Sales Only)

The moduli spaces M of surfaces of general type with a fixed topological type are known to have several connected components: there is a map (pi)(sub 0) (M) (yields) Diff, where Diff is the set of differentiable types of 4-manifolds. The unsolved question is whether this map is injective or not. The simplest surfaces of general type for which the moduli space is known to be disconnected are the so called Noether-Horikawa surfaces, for which one should try to calculate the Donaldson differentiable invariants. GOOD METRIC SPACES WITHOUT GOOD PARAMETERIZATIONS
S. Semmes Jan. 1995 68 p Sponsored by National Science Foundation Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-208427; IHES/M/95/2) Avail: CASI HC A04

A classical problem in geometric topology is to recognize when a topological space is a topological manifold. This paper addresses the question of when a metric space admits a quasisymmetric parameterization by providing counterexamples to the obvious optimistic conjectures, or, in other words, by providing examples of spaces with many Euclidean-like properties which are nonetheless substantially different from Euclidean geometry. These examples are geometrically self-similar versions of classical topologically self-similar examples from geometric topology, and they can be realized as codimension 1 subsets of Euclidean spaces. Unlike earlier examples going back to Rickman, these sets enjoy good bounds on their geodesic distance functions and good mass bounds (Ahlfors regularity). They are also smooth except for reasonably tame degenerations near small sets, they are uniformly rectifiable, and they have good properties in terms of analysis (like Sobolev and Poincare' inequalities). The construction also produces uniform domains which have many nice properties but which are not quasiconformally equivalent to balls. NTIS

HIGHER SCHWARZIAN OPERATORS AND COMBINATORICS OF SCHWARZIAN DERIVATIVE
H. Tamanoi Dec. 1994 26 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-208435; IHES/M/94/67) Avail: CASI HC A03

A family of Mobius invariant nonlinear differential operators (higher Schwarzian operators) is constructed in the context of the best Mobius approximations of analytic functions in one complex variable. Viewing the Schwarzian equation purely algebraically, we obtain a sequence of polynomials (Schwarzian polynomials) with positive integral coefficients expressing the higher Schwarzian operators in terms of derivatives of the classical Schwarzian derivative, and vice versa. These Schwarzian polynomials can be expressed in terms of the partial Bell polynomials. Integrality, positivity, and negativity properties of the Taylor coefficients of solutions to the Schwarzian equation are shown. The higher Schwarzian operators allow us to prove that any Mobius invariant differential operators can be derived from the classical Schwarzian derivative. In the Appendix, we give examples of Schwarzian polynomials. NTIS

QUASI-PERIODIC SOLUTIONS OF HAMILTONIAN PERTURBATIONS OF 2D LINEAR SCHROEDINGER EQUATIONS
J. Bourgain Jan. 1995 36 p
(PB95-208443; IHES/M/95/1) Avail: CASI HC A03/MF A01

This paper is a continuation of the author's work on constructing periodic and quasi-periodic solutions of Hamiltonian perturbations of linear PDE's (with periodic boundary conditions). The method used for this purpose was initiated in the work of Craig and Wayne for 1D-equations and time periodic solutions. It is an infinite dimensional phase space version of the Liapunov-Schmidt argument for the construction of periodic solutions. The basic idea of the Liapunov-Schmidt scheme consists in splitting the problem in a resonant finite dimensional piece given by the Q-equation and the remainder of the problem, the P-equation, which is infinite dimensional and contains the small divisors issues. To achieve frequency variation, we will rely on outer parameters contained in the equation rather than amplitude-frequency modulation depending on the nonlinear term. The model equation considered here is the nonlinear Schrodinger equation. NTIS

THE ITERATION FORMULA OF THE MASLOV-TYPE INDEX THEORY WITH APPLICATIONS TO NONLINEAR HAMILTONIAN SYSTEMS
Dong Di (Nankai Univ., Tiangjin, China.) and Yiming Long Oct. 1994 81 p Sponsored by YTF of Education Comm.; and NNSF of China
(DE95-613379; IC-94/318) Avail: CASI HC A05/MF A01 (US Sales Only)

In this paper, the iteration formula of the Maslov-type index theory for linear Hamiltonian systems with continuous periodic and symmetric coefficients is established. This formula yields a new method to determine the minimality of the period for solutions of nonlinear autonomous Hamiltonian systems via their Maslov-type indices. Applications of this formula give new results on the existence of periodic solutions with prescribed minimal period for such systems. DOE

USE OF ELEMENT-BY-ELEMENT PRECONDITIONERS TO SOLVE LARGE SCALE PARTIALLY SEPARABLE OPTIMIZATION PROBLEMS
M. J. Dayde, J. Y. LExcellent, and N. I. M. Gould Jan. 1995 33 p Prepared in cooperation with Centre Europeen Recherche et de Formation Advanceen Calcul Scientific, and CNRS, Toulouse, France
(PB95-195772; RAL-95-010) Avail: Issuing Activity (National Technical Information Service (NTIS))

We study the solution of large-scale nonlinear optimization problems by methods which aim to exploit their inherent structure. In particular, we consider the all-pervasive property of partial separability, first studied by Griewank and Toint (1982b). A typical minimization method for nonlinear optimization problems approximately solves a sequence of simplified linearized subproblems. In this paper, we explore how partial separability may be exploited by iterative methods for solving these subproblems. We particularly address the issue of computing effective preconditioners for such iterative methods. Numerical experiments indicate the effectiveness of these preconditioners on large-scale examples. POTENTIAL INTEGRAL EQUATIONS OF THE 2D LAPLACE OPERATOR IN WAVELET BASIS
Mihai Dorobantu [1994] 34 p Prepared in cooperation with Stockholm Univ., Sweden
(TRITA-NA-9401) Avail: CASI HC A03/MF A01

In this paper we solve the Laplace equation by solving a boundary integral equation in a wavelet basis. The idea of solving integral equations using a hierarchical approach is used in the Multipole method and

Wavelet-Galerkin methods in the non-standard form. Due to the orthogonality of the wavelet transform, the discrete linear systems preserve their good conditioning while their sparse structures speed up iterative solvers. We investigate the link between the two multi-scale methods and the convergence of Wavelet Galerkin discretizations. The behaviour of GCR algorithms under wavelet transformations and in non-standard form is investigated. Finally we analyze the optimal choice of Daubechies filters in the non-standard form and describe some numerical experiments. Author

ENHANCEMENTS TO THE SSME TRANSFER FUNCTION MODELING CODE Interim Report
R. Dennis Irwin, Jerrel R. Mitchell, David L. Bartholomew, and Russell D. Glenn Jul. 1995 59 p
(Grant NAG8-1041)
(NASA-CR-198957; NAS 1.26:198957) Avail: CASI HC A04/MF A01

This report details the results of a one year effort by Ohio University to apply the transfer function modeling and analysis tools developed under NASA Grant NAG8-167 (Irwin, 1992), (Bartholomew, 1992) to attempt the generation of Space Shuttle Main Engine High Pressure Turbopump transfer functions from time domain data. In addition, new enhancements to the transfer function modeling codes which enhance the code functionality are presented, along with some ideas for improved modeling methods and future work. Section 2 contains a review of the analytical background used to generate transfer functions with the SSME transfer function modeling software. Section 2.1 presents the 'ratio method' developed for obtaining models of systems that are subject to single unmeasured excitation sources and have two or more measured output signals. Since most of the models developed during the investigation use the Eigensystem Realization Algorithm (ERA) for model generation, Section 2.2 presents an introduction of ERA, and Section 2.3 describes how it can be used to model spectral quantities. Section 2.4 details the Residue Identification Algorithm (RID) including the use of Constrained Least Squares (CLS) and Total Least Squares (TLS). Most of this information can be found in the report (and is repeated for convenience). Section 3 chronicles the effort of applying the SSME transfer function modeling codes to the a51p394.dat and a51p1294.dat time data files to generate transfer functions from the unmeasured input to the 129.4 degree sensor output. Included are transfer function modeling attempts using five methods. The first method is a direct application of the SSME codes to the data files and the second method uses the underlying trends in the spectral density estimates to form transfer function models with less clustering of poles and zeros than the models obtained by the direct method. In the third approach, the time data is low pass filtered prior to the modeling process in an effort to filter out high frequency characteristics. The fourth method removes the presumed system excitation and its harmonics in order to investigate the effects of the excitation on the modeling process. The fifth method is an attempt to apply constrained RID to obtain better transfer functions through more accurate modeling over certain frequency ranges. Section 4 presents some new C main files which were created to round out the functionality of the existing SSME transfer function modeling code. It is now possible to go from time data to transfer function models using only the C codes; it is not necessary to rely on external software. The new C main files and instructions for their use are included. Section 5 presents current and future enhancements to the XPLOT graphics program which was delivered with the initial software. Several new features which have been added to the program are detailed in the first part of this section. The remainder of Section 5 then lists some possible features which may be added in the future. Section 6 contains the conclusion section of this report. Section 6.1 is an overview of the work including a summary and observations relating to finding transfer functions with the SSME code. Section 6.2 contains information relating to future work on the project. Author (revised)

REDUCED HEAT KERNELS ON NILPOTENT LIE GROUPS
A. F. M. terElst and D. W. Robinson Aug. 1994 42 p
(PB95-206926; RANA-94-16) Avail: CASI HC A03/MF A01

Let U be a basis representation of an irreducible unitary representation of a nilpotent Lie group G in L(sub 2)(R(sub k)) and let dU denote the representation of the Lie algebra g obtained by differentiation. If b(sub 1), ..., b(sub d) is a basis of g and B(sub i) = dU (b(sub i)) we consider the operators H = - Summation from i,j = 1 to d, of (C(sub ij)B(sub i)B(sub j)) + Summation, i = 1 to d, of (C(sub i)B(sub i)) where C = (C(sub ij)) is a real symmetric strictly positive matrix and C(sub i) is included in C. Then H generates a continuous semigroup S, holomorphic in the open right half-plane, with a reduced kernel Kappa defined by (S(sub z)Phi)(x) = integral over R(sup k) of dy Kappa(sub z)(x;y) Phi(y). We prove Gaussian off-diagonal bounds and 'exponential' on-diagonal bounds for Kappa. NTIS

FOURIER ANALYSIS OF A ROBUST MULTIGRID METHOD FOR CONVECTION-DIFFUSION EQUATIONS
A. A. Reusken Sep. 1994 38 p
(PB95-197091; RANA-94-17) Avail: CASI HC A03/MF A01

We consider a two-grid method for solving 2D convection-diffusion problems. The coarse grid correction is based on approximation of the Schur complement. As a preconditioner of the Schur complement, we use the exact Schur complement of modified fine grid equations. We assume constant coefficients and periodic boundary conditions and apply Fourier analysis. We prove an upper bound for the spectral radius of the two-grid

iteration matrix that is smaller than one and independent of the mesh size, the convection/diffusion ratio and the flow direction; i.e. we have a (strong) robustness result. Numerical results illustrating the robustness of the corresponding multigrid W-cycle are given. NTIS

A TURBULENCE MODULE FOR THE NPARC CODE
J. Zhu and T.-H. Shih Jun. 1995 12 p Presented at the 31st Joint Propulsion Conference and Exhibit, San Diego, CA, 10-12 Jul. 1995; sponsored by AIAA, ASME, SAE, and ASEE
(Contract NCC3-370; RTOP 505-90-5K)
(NASA-CR-198358; E-9745; NAS 1.26:198358; ICOMP-95-12; CMOTT-95-1; AIAA Paper 95-2612) Avail: CASI HC A03/MF A01

A turbulence module is developed for the 2D version of the NPARC code which is currently restricted to planar or axisymmetric flows without swirling. Four turbulence models have been built into the module: Baldwin-Lomax, Chien, Shih-Lumley and CMOTT models. The first is a mixing-length eddy-viscosity model which is mainly used for initialization of computational fields and the last three are the low Reynolds number two-equation models. Unlike chien's model, both the Shih-Lumley and CMOTT models do not involve the dimensionless wall distance y(sup +), an advantage for separated flow calculations. Contrary to the NPARC and most other compressible codes, the non-delta form of transport equations is used which leads to a simpler linearization and is more effective than using the delta form in ensuring the positiveness of the turbulent kinetic energy and its dissipation rate. To reduce numerical diffusion while maintaining necessary stability, a second-order accurate and bounded scheme is used for the convective terms of the turbulent transport equations. This scheme is implemented in a deferred correction manner so that the main coefficients of the resulting difference equations are always positive, thus making the numerical solutions process unconditionally stable. The system of equations is solved via a decoupled method and by the alternating direction TDMA of Thomas. The module can be easily linked to the NPARC code for turbulent flow calculations. Author

(AD-A290310; ASC-TR-051-3; ARI-RN-95-03) Avail: CASI HC A04/MF A01

Metacognitive skills that involve monitoring and control of cognitive skills like problem solving develop in expert executives and lead to great improvement in the problem-solving process. In this report, we review theory and research on metacognition to construct a conceptual model that has three characteristics: (1) it shows the interrelationship of metacognitive skills and cognitive task performances, (2) it suggests the most valid assessment techniques for the measurement of metacognitive skills, and (3) it shows the development of metacognitive skills. From the third characteristic, we designed a training program to accelerate the acquisition of metacognitive skills in officers in the U.S. Armed Forces. From the second characteristic, we will construct proficiency tests of metacognitive skills for measuring these skills in commanders at various levels of professional development; the tests will also be used to evaluate the effectiveness of the training. PSEUDO-TIME METHODS FOR CONSTRAINED OPTIMIZATION PROBLEMS GOVERNED BY PDE Final Report
Shlomo Taasan May 1995 16 p Submitted for publication in SIAM Journal on Optimization
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-195081; ICASE-95-32; NAS 1.26:195081) Avail: CASI HC A03/MF A01

In this paper we present a novel method for solving optimization problems governed by partial differential equations. Existing methods are gradient information in marching toward the minimum, where the constrained PDE is solved once (sometimes only approximately) per each optimization step. Such methods can be viewed as a marching techniques on the intersection of the state and costate hypersurfaces while improving the residuals of the design equations per each iteration. In contrast, the method presented here march on the design hypersurface and at each iteration improve the residuals of the state and costate equations. The new method is usually much less expensive per iteration step since, in most problems of practical interest, the design equation involves much less unknowns that that of either the state or costate equations. Convergence is shown using energy estimates for the evolution equations governing the iterative process. Numerical tests show that the new method allows the solution of the optimization problem in a cost of solving the analysis problems just a few times, independent of the number of design parameters. The method can be applied using single grid iterations as well as with multigrid solvers. Author

NUMERICAL STABILITY INVESTIGATIONS OF PROCESSES FOR SOLVING LINEAR INITIAL VALUE PROBLEMS
J. L. M. vanDorsselaer Oct. 1994 35 p Sponsored by Nederlandse Organisatie voor Wetenschappelijk Onderzoek, The Hague
(PB95-207023) Avail: CASI HC A03/MF A01

An algorithm is presented which can be used to verify a priori whether a given numerical process for solving a linear initial value problem will behave stably or not. This algorithm, which is based on so-called M-numerical ranges and resolvent conditions, can give reliable results in cases where the classical eigenvalue criterion fails. The algorithm will be applied to investigate the stability of numerical schemes for solving an evolution problem for a convection-diffusion equation. The spatial discretization of the convection-diffusion equation is based on a spectral collocation method. For different types of collocation points the stability will be investigated. A theoretical result concerning stability in case of the Legendre-Gauss-Lobatto points is also given. NTIS

EFFECT OF THE STOPPING OF THE NEWTON ITERATION IN IMPLICIT LINEAR MULTISTEP METHODS
M. N. Spijker Aug. 1994 26 p
(PB95-207056) Avail: CASI HC A03/MF A01

This paper concerns the application of implicit, linear multistep methods in the numerical solution of stiff, nonlinear initial value problems. Previously the (modified) Newton iteration for coping with the nonlinear equations connected with the implicitness of the multistep methods was studied. Formulas were found for the order of the corresponding Newton stopping errors. It was later shown that for a class of strongly nonlinear initial value problems, estimates for the Newton stopping errors are in force with an order that is even lower. In the present paper the authors find that the actual effect of the stopping of the Newton iteration differs remarkably from what one might expect. The effect turns out to be of a higher order. The authors find that the original order is reliable for stiff problems that

are mildly nonlinear. Moreover, for stiff problems that are strongly nonlinear, the order of the accumulated effect of all Newton stopping errors turns out to be greater (by one) than the order which one may expect. NTIS

(Contract W-7405-eng-36)
(DE95-010886; LA-UR-95-1159; CONF-9505195-3) Avail: CASI HC A03/MF A01

Careful assessment of the results of a calculation by the code itself can reduce mistakes in the problem setup and execution. MCNP has over four hundred error messages that inform the user of FATAL or WARNING errors that have been discovered during the processing of just the input file. The latest version, MCNP4A, now performs a self assessment of the calculated results to aid the user in determining the quality of the Monte Carlo results. MCNP4A, which was released to RSIC in October 1993, contains new analyses of the MCNP Monte Carlo calculation that provide simple user WARNING's for both criticality and fixed source calculations. The goal of the new analyses is to provide the MCNP criticality practitioner with enough information in the output to assess the validity of the k(sub eff) calculation and any associated tallies. The results of these checks are presented in the k(sub eff) results summary page, several k(sub eff) tables and graphs, and tally tables and graphs. Plots of k(sub eff) at the workstation are also available as the problem is running or in a postprocessing mode to assess problem performance and results. DOE

REPRESENTATION OF FEEDBACK OPERATORS FOR HYPERBOLIC SYSTEMS Final Report
John A. Burns (Virginia Polytechnic Inst., Blacksburg, VA.) and Belinda B. King (Oregon State Univ., Corvallis, OR.) May 1995 14 p
(Contract NAS1-19480; RTOP 505-90-52-01)
(NASA-CR-198171; NAS 1.26:198171; ICASE-95-45) Avail: CASI HC A03/MF A01

We consider the problem of obtaining integral representation of feedback operators for damped hyperbolic control systems. We show that for the wave equation with Kelvin-Voigt damping and non-compact input operator, the feedback gain operator is Hilbert-Schmidt. This result is then used to provide an explicit integral representation for the feedback operator in terms of functional gains. Numerical results are given to illustrate the role that damping plays in the smoothness of these gains. Author

A STUDY OF NUMERICAL SOLUTIONS OF CONSERVATION LAWS
Gunilla Johansson [1993] 60 p Prepared in cooperation with Stockholm Univ., Sweden
(TRITA-NA-9315) Avail: CASI HC A04/MF A01

We analyze the influence of artificial viscosity introduced by first order methods for nonlinear hyperbolic problems with solutions containing shocks. Numerical computations of two different scalar equations and the gasdynamic equations are presented. We introduce a method, constructed such that numerical solutions of the wave equation are well behaved also when the solutions contain discontinuities. The wave equation serves as a model problem for the Euler equations when the solution contain a contact discontinuity. Numerical results imply that the method gives well behaved solutions both for discontinuous and smooth initial data. Author

In another paper we showed that every Frobenius algebra over a commutative ring determined a solution of the quantum Yang-Baxter equation. Applying this result to Hopf algebras over commutative rings which are finitely generated and projective as modules, we obtain an explicit formula for this solution. It turns out that this solution plays an important role in the structure theory of Hopf algebras over commutative rings. Making use of its properties, we characterize separable Hopf algebras. As a corollary it is shown that the dimension of a simple module over a semisimple Hopf algebra over an algebraically closed field is not divisible by its characteristic. Some results on order of antipode are also obtained. NTIS

POISSON APPROXIMATION USING THE STEIN-CHEN METHOD AND COUPLING: NUMBER OF EXCEEDANCES OF A DISCRETE-TIME-CHI-SQUARED PROCESS
M. Raab 1995 46 p
(PB95-212205; TRITA-MAT-1995/MS-1) Avail: CASI HC A03/MF A01

Consider a discrete-time-chi-squared process, i.e. a process defined as the sum of squares of independent and identically distributed normal processes. Count the number of values that exceeds a certain level. Let this level grow together with the number of time-points considered so that the expected number of points above the level remains fixed. It is shown that the number of exceeding points converges in distribution to a Poisson distribution, if the dependence in the underlying normal processes is not too strong. By using the coupling approach of the Stein-Chen method, both limit theorems and rates of convergence can be obtained. Finally the convergence is illustrated by numerical examples on ARMA-processes. FORMALIZATION OF THE RAMIFIED TYPE THEORY
T. Laan 1 Sep. 1994 49 p
(PB95-206785) Avail: CASI HC A03/MF A01

We give a formalization of the ramified type theory as described in the Principia Mathematica, trying to keep it as close as possible to the ideas of the Principia. As an alternative, distancing ourselves from the Principia, we express notions from the ramified type theory in a lambda calculus style, thus clarifying the type system in a contemporary setting. Both formalizations are inspired by current developments in research on type theory and typed lambda calculus. In these formalizations, and also when defining 'truth', we will need the notion of substitution. As substitution is not formally defined in the Principia, we have to define it ourselves. NTIS

A NEW GOODNESS-OF-FIT TEST FOR THE GAMMA DISTRIBUTION BASED ON SAMPLE SPACINGS FROM COMPLETE AND CENSORED SAMPLES M.S. Thesis
Huseyin Duman Mar. 1995 168 p
(AD-A293875; AFIT/GOR/ENC/ENS/95M-08) Avail: CASI HC A08/MF A02

This thesis studies a new goodness-of-fit test for the gamma distribution with known shape parameter. This test statistic, Z^*, is based on spacings from complete or censored samples. The size of samples varied between 5 and 35. The critical value tables were generated for the Z^* test statistic for complete and censored samples. The critical values were obtained for five different significance levels: 0.20 0.15, 0.10, 0.05, and 0.01. An extensive power study, containing 50,000 Monte Carlo runs was conducted using nine alternative distributions, H(a). It was observed that the Z^* test statistic was more powerful against certain alternatives which are less skewed than the gamma distribution with a given shape parameter. A regression between the critical values and the sample size, shape parameter, significance levels and degree of censoring was established. The power of the Z^* test statistic is compared to the powers of the competing test statistics (K-S, W sub 2, and A-D). This thesis reveals that the Z^* test statistic is a directional test. This feature may be utilized to attain higher power values by coupling the Z^* and the A-D test statistics in a sequential test. DTIC

MULTIPOINT QUADRATIC APPROXIMATION FOR NUMERICAL OPTIMIZATION M.S. Thesis
Michael A. Blaylock 21 Mar. 1995 111 p
(AD-A293837; AFIT/GA/ENY/95M-1) Avail: CASI HC A06/MF A02

A quadratic approximation for nonlinear functions is developed in order to realize computational savings in solving numerical optimization problems. Function and gradient information accumulated from multiple design points during the iteration history is used in estimating the Hessian matrix. The approximate Hessian matrix is the available for a second order Taylor series approximation to the functions of interest. Several truss and frame models will be used to demonstrate the effectiveness of the new Multipoint Quadratic Approximation (MQA) in solving structural optimization problems. DTIC

REMOVAL OF THE ENERGY DEPENDENCE FROM THE RESOLVENT LIKE ENERGY DEPENDENT INTERACTIONS
A. K. Motovilov 1994 20 p
(DE95-613385; JINR-E-5-94-259) Avail: CASI HC A03/MF A01 (US Sales Only)

The spectral problem $(A + V(z))psi = z\ psi$ is considered where main Hamiltonian A is a self-adjoint operator of sufficiently arbitrary nature. The perturbation $V(z) = -B(A'-z)(sup\ -1)\ B(sup\ *)$ depends on the energy z as resolvent of another self-adjoint operator A'. The latter is usually interpreted as Hamiltonian describing an internal structure of physical system. The operator B is assumed to have a finite Hilbert-Schmidt norm. The conditions are formulated when one can replace the perturbation V(z) with an energy independent 'potential' W such that the Hamiltonian $H = A + W$ has the same spectrum (more exactly a part of spectrum) and the same eigenfunctions as the initial spectral problem. The Hamiltonian H is constructed as a solution of the non-linear operator equation $H = A + V(H)$. It is established that this equation is closely connected with the problem of searching for invariant subspaces for the Hamiltonian $H = A(sub\ B)(sup\ *)\ B(sub\ A)'$. The orthogonality and expansion theorems are proved for eigenfunction systems of the Hamiltonian $H = A+W$. Scattering theory is developed for this Hamiltonian in the case when operator A has continuous spectrum. DOE

THE COMPLEXITY AND APPROXIMABILITY OF FINDING MAXIMUM FEASIBLE SUBSYSTEMS OF LINEAR RELATIONS
Edoardo Amaldi (Eidgenoessische Technische Hochschule, Lausanne, Switzerland.) and Viggo Kann [1993] 31 p Prepared in cooperation with Stockholm Univ., Sweden
(TRITA-NA-9313) Avail: CASI HC A03/MF A01

We study the combinatorial problem which consists, given a system of linear relations, of finding a maximum feasible subsystem, that is a solution satisfying as many relations as possible. The computational complexity of this general problem, named MAX FLS, is investigated for the four types of relations =, greater than or equal to, greater than, and does not equal. Various constrained versions of MAX FLS, where a subset of relations must be satisfied or where the variables take bounded discrete values, are also considered. We establish the complexity of solving these problems optimally and, whenever they are intractable, we determine their degree of approximability. MAX FLS with =, greater than or equal to, or greater than relations is NP-hard even when restricted to homogeneous systems with bipolar coefficients, whereas it can be solved in polynomial time for nonequivalent relations with real coefficients. The various NP-hard versions

of MAX FLS belong to different approximability classes depending on the type of relations and the additional constraints. We show that the range of approximability stretches from MAX SNP-hard problems which can be approximated within a constant but not within every constant unless P=NP, to MAX PB-complete ones that are as hard to approximate as all maximization problems with polynomially bounded objective functions. While MAX FLS with equations and integer coefficients cannot be approximated within rho(exp epsilon) for some epsilon greater than 0 where rho is the number of relations, the same problem over GF(q) for a prime q can be approximated within q but not within q(exp epsilon) for some epsilon greater than 0. MAX FLS with strict or nonstrict inequalities can be approximated within 2 but not within every constant factor. Our results also provide strong bounds on the approximability of two variants of MAX FLS with greater than and greater than relations that arise when training perceptrons, which are the building blocks of artificial neural networks. Dissert. Abstr.

A UNIFIED INTERPRETATION OF SINGULAR AND NEAR-SINGULAR INTEGRALS IN THE BOUNDARY ELEMENT METHOD Ph.D. Thesis
Dan Rosen 1993 207 p
(ISBN-0-315-86297-1) Avail: Univ. Microfilms Order No. DANN86297

The computation of element integrals is of major importance to the Boundary Element Method (BEM). This thesis provides a unified framework for understanding and computing a large class of singular and near-singular integrals. In the continuation approach, the singular surface integrals, of the type which arise in the BEM, are viewed merely as 'continuations' of non-singular (but perhaps near-singular) ones. Thus, in this approach, singular integrals are obtained from a limiting process in which the singularity of the integrand originally lies outside the integration domain and is gradually moved towards it. The analysis presents a clear and intuitive picture of the behavior of these integrals, which leads to general efficient formulae for singular and near-singular integral evaluation, the former being a special case of the latter. In addition, we obtain necessary and sufficient conditions, herein referred to as 'gauge conditions', that guarantee the boundedness of the continuation singular integrals. It is further shown that, when these conditions are met, the continuation singular integral encompasses the classical cases of Cauchy principal value integrals, jump terms, and Hadamard finite part. Numerical examples, which illustrate the computational advantages of the continuation formulae, are presented. For flat integration surfaces, the continuation approach exploits the functional homogeneity of many Green's functions. The analysis is expanded to more general integrands and to curved integration domains by using the series expansion/subtraction ideas, popular in the BEM literature. It is shown that this expansion is greatly simplified by first mapping the integral to the tangent plane at the (near-)singularity, instead of to the parametric element. The continuation approach is also presented for the case when the singularity lies on, or close to, a corner (or non-smooth part) of the domain. This analysis is of considerable practical importance since it overcomes the difficulties and limitations of strictly analytical techniques. Moreover, it is shown that the gauge conditions of the singular integrals impose some constraints on the functional approximation of the source's densities, in BEM discretizations. A systematic method to obtain these constraints and to incorporate them into the formulation of general problems is presented. Dissert. Abstr.

PRESERVATION THEOREMS ON FINITE STRUCTURES
Michel Hebert (American Univ., Cairo, Egypt.) Sep. 1994 7 p
(DE95-613442; IC-94/273) Avail: CASI HC A02/MF A01 (US Sales Only)

This paper concerns classical preservation results applied to finite structures. We consider binary relations for which a strong form of preservation theorem (called strong interpolation) exists in the usual case. This includes most classical cases: embeddings, extensions, homomorphisms into and onto, sandwiches, etc. We establish necessary and sufficient syntactic conditions for the preservation theorems for sentences and for theories to hold in the restricted context of finite structures. We deduce that for all relations above, the restricted theorem for theories hold provided the language is finite. For the sentences the restricted version fails in most cases; in fact the 'homomorphism into' case seems to be the only possible one, but the efforts to show that have failed. We hope our results may help to solve this frustrating problem; in the meantime, they are used to put a lower bound on the level of complexity of potential counterexamples. DOE

A MODIFICATION TO THE GMRES METHOD FOR ILL-CONDITIONED LINEAR SYSTEMS
J. C. Meza Apr. 1995 21 p
(Contract DE-AC04-94AL-85000)
(DE95-010661; SAND-95-8220) Avail: CASI HC A03/MF A01

This paper concerns the use of a method for the solution of ill-conditioned linear systems. We show that the Generalized Minimum Residual Method (GMRES) in conjunction with a truncated singular value decomposition can be used to solve large nonsymmetric linear systems of equations which are nearly singular. Error bounds are given for the right singular vectors and singular values computed. A consequence of the error bounds results in a method for computing some of the singular values and right singular vectors for large matrices. DOE

NEWTON RAPHSON METHOD, SCALING AT FRACTAL BOUNDARIES AND MATHEMATICA
Ajay Kumar Bisoi Sep. 1994 19 p
(DE95-613374; IC-94/268) Avail: CASI HC A03/MF A01 (US Sales Only)

The basins of convergence of cubic polynomials having real roots are studied using Newton Raphson iterative method. The limiting value for the ratio of basin segments for equispaced roots is explained. An algorithm is presented for computing the basin boundaries on the real axis which obviates the necessity of taking recourse to extensive search. Mathematica programs have been developed to help in the above study and also to depict the basins in the complex plane. DOE

DATA REDUCTION OF PIECEWISE LINEAR CURVES
E. Arge and M. Daehlen 31 Aug. 1994 26 p Prepared in cooperation with Oslo Univ. and the Royal Norwegian Council for Scientific and Industrial Research
(PB95-212270; STF33-A94042) Avail: Issuing Activity (National Technical Information Service (NTIS))

The authors present and study two new algorithms for data reduction or simplification of piecewise linear plane curves. Given a curve P and a tolerance epsilon greater than or equal to 0, both methods determine a new curve Q, with few vertices, which is at most epsilon in Hausdorff distance from P. The methods differ from most existing methods in that they do not require a vertex in Q to be a vertex in P. Several examples are given where the authors show that the methods presented here compare favorably to other methods found in the literature. The authors also show how the vertices of a curve can be reordered so that the first, say n, vertices of the reordered sequence form an approximation to the curve itself. NTIS

ANALYSIS OF VARIATION EMBEDDING TESTS WITH 17 MM DOWEL: DENSIFIED VENEER WOOD FOREST PROJECT, PART 7
A. J. M. Leijten Jan. 1994 215 p Limited Reproducibility: More than 20% of this document may be affected by microfiche quality
(PB95-206876) Avail: CASI HC A10

The aim of the research was to determine some physical and mechanical properties of densified veneer wood for structural purposes. Preliminary tests with densified veneer wood (dvw) locally glued to the surface of the timber members of joints showed an appreciable improvement of the joint strength stiffness and ductility capacity. As the improvement proved to be interesting for industry further research was initiated. The joints fit for this reinforcement are mainly build-up joints as applied in trusses and portal frames. The joint members are connected by means of mechanical fasteners like dowel type fasteners. Densified veneer wood (dvw) for this application is cross-wise layered. This report is part of a set with the statistical analysis of all test data. It deals with the analysis of embedding test data on 8 mm thick dvw. NTIS

ASPECTS OF THE SEARCH TIME IN BINARY SEARCH TREES MODIFIED ACCORDING TO THE MOVE-TO-ROOT HEURISTIC
J. Bodell 1994 52 p
(PB95-212148; TRITA-MAT-1994-48) Avail: CASI HC A04/MF A01

The search time in a binary search tree organized according to the self-organizing move-to-root heuristic is considered. Supposing that the records in the tree are requested independently with constant probabilities, the mean, variance and two different (but equivalent) expressions for the generating function for the search time in stationarity are derived by embedding in Poisson processes. We look for the 'worst' request probabilities, i.e., those that maximize the search time, and rearrange them into a 'best' permutation that minimizes the search time. Mean, variance and probability functions are computed numerically for some illustrating request probability distributions and their 'best' and 'worst' permutations. Finally, an approximating distribution is found for the search time in the special case arising when all of the request probabilities are equal. NTIS

NONLINEAR TIME SERIES ANALYSIS M.S. Thesis
James A. Stewart Mar. 1995 91 p
(AD-A293841; AFIT/GOA/ENG/95M-01) Avail: CASI HC A05/MF A01

This thesis applies neural network feature selection techniques to multivariate time series data to improve prediction of a target time series. Two approaches to feature selection are used. First, a subset enumeration method is used to determine which financial indicators are most useful for aiding in prediction of the S&P 500 futures daily price. The candidate indicators evaluated include RSI, Stochastics and several moving averages. Results indicate that the Stochastics and RSI indicators result in better prediction results than the moving averages. The second approach to feature selection is calculation of individual saliency metrics. A new decision boundary-based individual saliency metric, and a classifier independent saliency metric are developed and tested. Ruck's saliency metric, the decision boundary based saliency metric, and the classifier independent saliency metric are compared for a data set consisting of the RSI and Stochastics indicators as well as delayed closing price values. The decision based metric and the Ruck metric results are similar, but the classifier independent metric agrees with neither of the other metrics. The nine most salient features, determined by the decision boundary based metric, are used to train a neural network and the results are presented and compared to other published results. DTIC

NONPARAMETRIC RECOGNITION OF NONRIGID MOTION
Ramprasad B. Polana and Randal C. Nelson Mar. 1995 31 p Sponsored in part by an ARPA subcontract from the University of Maryland Limited Reproducibility: More than 20% of this document may be affected by poor print
(Contract N00014-93-1-0221)
(AD-A293630; TR-575) Avail: Issuing Activity (Defense Technical Information Center (DTIC))

The recognition of nonrigid motion, particularly that arising from human movement (and by extension from the locomotory activity of animals) has typically made use of high-level parametric models representing the various body parts (legs, arms, trunk, head etc.) and their connections to each

other. Such model-based recognition has been successful in some cases; however, the methods are often difficult to apply to real-world scenes, and are severely limited in their generalizability. The first problem arises from the difficulty of acquiring and tracking the requisite model parts, usually specific joints such as knees, elbows or ankles. This generally requires some prior high-level understanding and segmentation of the scene, or initialization by a human operator. The second problem, with generalization, is due to the fact that the human model is not much good for dogs or birds, and for each new type of motion, a new model must be hand-crafted. In this paper, we show that the recognition of human or animal locomotion, and, in fact, any repetitive activity can be done using low-level, non-parametric representations. Such an approach has the advantage that the same underlying representation is used for all examples, and no individual tailoring of models or prior scene understanding is required. We show in particular, that repetitive motion is such a strong cue. That the moving actor can be segmented, normalized spatially and temporally, and recognized by matching against a spatio-temporal template of motion features. DTIC

A HYPOTHESIS-TESTING APPROACH TO DISCRIMINANT ANALYSIS WITH MIXED CATEGORICAL AND CONTINUOUS VARIABLES WHEN DATA ARE MISSING
J. W. Miller, W. A. Woodward, H. L. Gray, and G. D. McCartor Jul. 1994 41 p
(Contract F19628-93-C-0199; ARPA Order A128)
(AD-A293714; SMU-DS-TR273; PL-TR-94-2241; SR-1) Avail: CASI HC A03/MF A01

In this report we consider the problem of discriminant analysis with discrete (categorical) and continuous variables with data missing at random. We use a hypothesis-testing approach based on the generalized likelihood ratio as proposed by Baek, et al. We use bootstrapping to determine critical values in order to control the Type 1 error rate. We present three algorithms for dealing with this case, each assuming a different model for the data: the INDICATOR algorithm replaces categorical variables with indicator variables, and treats these as if they were continuous, the FULL algorithm assumes a multinomial distribution for the discrete part, and a multivariate normal distribution (with mean and covariances depending on the discrete part) as the conditional distribution of the continuous part given the discrete part, and the COMMON algorithm assumes a multinomial distribution for the discrete part, and a multivariate normal distribution (with only the means depending on the discrete part) as the conditional distribution of the continuous part given the discrete part. (That is, a common covariance matrix is assumed across all multinomial cells.) The performance of these algorithms is compared through a simulation study. While the INDICATOR algorithm seems to have highest power, it also tends to display a higher Type 1 error rate than desired. The FULL and the COMMON algorithms have very similar power, but the COMMON algorithm appears to control the Type 1 error rate most effectively, and is least susceptible to problems occurring when some multinomial cells are sparsely represented. OPERATING SYSTEM SUPPORT FOR DISTRIBUTED MULTIMEDIA APPLICATIONS: A SURVEY OF CURRENT RESEARCH
T. M. Burkow Sep. 1994 43 p
(PB95-207096; Memo-INF-94-49) Copyright Avail: CASI HC A03/MF A01

The report examines current research, and general design characteristics in operating system support for multimedia. Generally, conventional operating systems do not provide adequate support for distributed multimedia applications. Important design aspects are: reducing the amount of data copying; lowering the number of kernel boundary crossings; and implementing efficient context switches between threads. Quality of Service (QoS) management is also an important aspect in the design, and furthermore, mechanisms for synchronization are needed. There are several projects working with operating system support for multimedia applications, some addressing file system design, some addressing kernel design and some both. NTIS

REPORT TO THE CHAIRMAN, LEGISLATION AND NATIONAL SECURITY SUBCOMMITTEE, COMMITTEE ON GOVERNMENT OPERATIONS, HOUSE OF REPRESENTATIVES. TACTICAL AIRCRAFT: F-15 REPLACEMENT IS PREMATURE AS CURRENTLY PLANNED
25 Mar. 1994 10 p
(GAO/NSIAD-94-118; B-253662) Avail: CASI HC A02/MF A01; GAO, PO Box 6015, Gaithersburg, MD 20877 HC

The F-22 program was initiated in 1981 to meet the evolving threat in the mid-1990's. This threat revolved around a fighter threat that had a significant quantitative advantage and was becoming more capable with the introduction of two new high performance fighters. Since the F-22 program entered full-scale development in 1991, the severity of the projected military threat in terms of quantities and capabilities has declined. Instead of confronting thousands of modern Soviet fighters, U.S. air forces are expected to confront potential adversary air forces that include few fighters that have the capability to challenge the F-15 - the U.S. front line fighter. The F-15 exceeds the most advanced threat system expected to exist. And no improvements will be made to the F-15 but the capability of the 'most advanced threat' assumes certain modifications. Further, analysis shows that the current inventory of F-15's can be economically maintained in a structurally sound condition until 2015 or later. Thus, the F-22's initial operational capability can be delayed 7 years and its planned production start date of 1996 can be postponed to a future date deemed appropriate by DOD to meet the new initial operational capability date.

AUTOMATIC VERIFICATION AND SYNTHESIS OF FINITE-STATE HARD REAL-TIME SYSTEMS Final Technical Report
David Dill 31 May 1994 8 p
(Contract N00014-91-J-1901)
(AD-A291279) Avail: CASI HC A02/MF A01

The goal is to develop computationally feasible automatic methods for the formal verification and synthesis of hard real-time systems. The current year's focus has been on making approximation methods work for more realistic system designs. Considerable effort has been invested in generalizing the approximation techniques in the hope that they can be used in other domains. The current algorithm works by successive approximation. It proceeds in a sequence of forward and backwards passes. It is consistently able to handle all of the examples attempted, including the difficult ethernet example of Weinberg and Zuck. In addition, an algorithm has been developed for handling 'skewed clock automata,' which allow timers that increase at variable rates, where only upper and lower bounds on the rates are known. CASI

COVARIANT PHASE SPACE FORMULATIONS OF SUPERPARTICLES AND SUPERSYMMETRIC WZW MODELS
G. Au and B. Spence Feb. 1994 15 p

(DE95-616278; UM-P-93/107) Avail: CASI HC A03/MF A01 (US Sales Only)

The Wess-Zumino-Witten (WZW) models are fundamental rational conformal field theories, and have a rich structure which has occasioned much interest. With regard to the further development of the formulation of this approach, as well as to the various applications of supersymmetric WZW models in superstring theories, the authors consider the question of whether one can generalize this covariant phase space formulation to the supersymmetric WZW models and discuss superparticles moving upon group manifolds. These systems share many of the important features of the supersymmetric WZW models. The WZW models are then discussed. It is shown that the full current algebras arise naturally for these models and the topological issues which arose in the bosonic case are found here with the same resolution. DOE

PLAQUETTE EXPANSION PROOF AND INTERPRETATION
N. S. Witte and Lloyd C. L. Hollenberg 2 Sep. 1993 19 p Submitted for publication in the Journal of Mathematical Physics
(DE95-616282; UM-P-93/87) Avail: CASI HC A03/MF A01 (US Sales Only)

The plaquette expansion, a general non-perturbative method for calculating the properties of lattice Hamiltonian systems, is established up to the first two orders for an arbitrary system. This method employs an expansion of the Lanczos coefficients, the tridiagonal Hamiltonian matrix elements or equivalently the continued fraction coefficients of the resolvent, in a descending series in the size of the system. The coefficients of this series are formed from the low order cumulants or connected Hamiltonian moments. The lowest order approximation in the plaquette expansion corresponds to a Gaussian model which is a consequence of the control limit theorem. DOE

Employing a theorem on lower bounds on the zeros of orthogonal polynomials, the plaquette expansion to order 1/N(sub p) of the tri-diagonal Lanczos matrix elements is solved for the ground state energy density in the infinite lattice limit. The resulting non-perturbative expression for the estimate of the energy density in terms of the connected coefficients to order (H(sup 4))(sub c) is completely general. This expression is applied to various Hamiltonian systems - the Heisenberg model in D dimensions and SU(2) and SU(3) lattice gauge theory in 3 + 1 dimensions. In all cases the analytic estimate to the energy density is not only a significant improvement on the trial state, but is typically accurate to a few percent. The energy density of the D-dimensional Heisenberg model is predicted to approach (epsilon)(sub 0)(Neel) - 1/8 for large D. In the case of SU(2) and SU(3) the specific heat derived from the energy density peaks at the correct strong to weak coupling transition. DOE

ELECTROWEAK INTERACTIONS ON THE LATTICE
Tien Dung Kieu Jul. 1994 6 p
(DE95-616287; UM-P-94/74; RCHEP-94/22) Avail: CASI HC A02/MF A01 (US Sales Only)

It is shown that the lattice fermion doubling phenomenon is connected to the chiral anomaly which is unique to the electroweak interactions. The chiral anomaly is the breaking of chiral gauge symmetry at the quantum level due to the quantum fluctuations. Such breaking, however, is undesirable and to be avoided. The preservation of gauge symmetry imposes stringent constraints on acceptable chiral gauge theory. It is argued that the constraints are unnecessary because the conventional quantization of chiral gauge theory has missed out some crucial contributions of the chiral interactions. The corrected quantization yields consistent theory in which there is no gauge anomaly and in which various mass terms can be introduced with neither the loss of gauge invariance nor the need for the Higgs mechaniam. The new quantization also provides a solution to the difficulty of how to model the electroweak interactions on the lattice. DOE

4-MANIFOLD TOPOLOGY 2: DWYER'S FILTRATION AND SURGERY KERNELS
M. H. Freedman and P. Teichner Feb. 1995 27 p Sponsored by National Science Foundation
(PB95-207940; IHES/M/95/12) Avail: CASI HC A03/MF A01

Even when the fundamental group is intractable (i.e. not 'good') many interesting 4-dimensional surgery problems have topological solutions. We unify and extend the known examples and show how they compare to the (presumed) counter examples by reference to Dwyer's filtration on second homology. The development brings together many basic results on the nilpotent theory of links. As a special case, a class of links only slightly smaller than 'homotopically trivial links' is shown to have (free) slices on their Whitehead doubles. NTIS

EXTENSION TO HIGHER DIMENSIONS OF THE JAESCHKE-EICKER RESULT ON THE STANDARDIZED EMPIRICAL PROCESS
J. H. J. Einmahl Sep. 1994 16 p
(PB95-206868; MEMO-COSOR-94-31) Avail: CASI HC A03/MF A01

The asymptotic distribution of the sup-norm of the heavily weighted empirical process is established in the multidimensional case. This theorem extends in particular the famous result in Jaeschke (1975, 1979) to higher dimensions. There is a striking difference between the behavior for higher dimensions and that for dimension one, especially the limiting distribution is now a simple transformation of a standard exponential random variable. THE 4-MANIFOLD TOPOLOGY 1: SUBEXPONENTIAL GROUPS

M. H. Freedman and P. Teichner Feb. 1995 21 p
(PB95-207957; IHES/M/95/11) Avail: CASI HC A03/MF A01

The technical lemma underlying the 5-dimensional topological s-cobordism conjecture and the 4-dimensional topological surgery conjecture is a purely smooth category statement about locating pi(sub 1)-null immersions of disks. These conjectures are theorems precisely for those fundamental groups ('good groups') where the pi(sub 1)-null disk lemma (NDL) is known. We expand the class of good groups to all groups of subexponential growth and those that can be formed from these by a finite number of application of two operations: (1) extension and (2) direct limit. Good finitely generated groups are amenable and as far as is known these may be all the amenable groups. NTIS

ARITHMETIC FEATURES OF RATIONAL CONFORMAL FIELD THEORY
I. T. Todorov Feb. 1995 29 p Prepared in cooperation with Bulgarian Academy of Sciences
(PB95-207908; IHES/P/95/10) Avail: CASI HC A03/MF A01

Rational conformal field theory (RCFT) gradually opened the way to an intrusion of number theoretic methods into mathematical physics. Intriguing parallels between V. Jones theory of subfactors and patterns of 2-dimensional (2D) critical behavior led to the introduction of lattice models labeled by Dynkin diagrams and to the A-D-E classification of A(1) current algebra and minimal conformal models. This work used number theoretic tools and triggered an interaction between the two fields. The trend continues in recent work on the role of Galois symmetry in the search for modular invariants and in applying the representation theory of affine superalgebras to number theoretic problems. The present paper displays (and makes use of) some number theoretic features of braid matrices and structure constants in RCFT models, that have remained unnoticed in otherwise comprehensive studies in the past. A METALLURGICAL APPROACH TOWARD ALLOYING IN RARE EARTH PERMANENT MAGNET SYSTEMS Ph.D. Thesis
Daniel James Branagan 23 Feb. 1995 274 p
(Contract W-7405-eng-82)
(DE95-010242; IS-T-1719) Avail: CASI HC A12/MF A03

The approach was developed to allow microstructural enhancement and control during solidification and processing. Compound additions of Group IVA, VA, or VIA transition metals (TM) and carbon were added to Nd2Fe14B (2-14-1). Transition metal carbides formed in IVA (TiC, ZrC, HfC) and Group VA (VC, NbC, TaC) systems, but not in the VIA system. The alloying ability of each TM carbide was graded using phase stability, liquid and equilibrium solid solubility, and high temperature carbide stability. Ti with C additions was chosen as the best system. The practically zero equilibrium solid solubility means that the Ti and C additions will ultimately form TiC after heat treatment which allows the development of a composite microstructure consisting of the 2-14-1 phase and TiC. Thus, the excellent intrinsic magnetic properties of the 2-14-1 phase remain unaltered and the extrinsic properties relating to the microstructure are enhanced due to the TiC stabilized microstructure which is much more resistant to grain growth. When Ti + C are dissolved in the liquid melt or solid phases, such as the glass or 2-14-1 phase, the intrinsic properties are changed; favorable changes include increased glass forming ability, reduced optimum cooling rate, increased optimum energy product, and enhanced nucleation kinetics of crystallization. GOLDEN TEN EQUATIONS OF MOTION
J. C. deVos and A. A. F. vandeVen Nov. 1994 28 p
(PB95-197927; RANA-94-24) Avail: CASI HC A03/MF A01

This paper employs a mechanical model to describe the motion of the ball in the drum during a game of Golden Ten. The result of this model is a set of differential equations. Provided that the values of the physical constants in the model are known, this set of equations can be solved numerically. The friction coefficients generate a problem here, because they have to be estimated by means of complementary experiments. After the numerical solution has been presented, the paper proceeds with a quest for an analytical solution. The system of equations is rewritten in terms of a set of small parameters--implicitly representing the friction coefficients and the drum's angle of inclination--and an analytical method is employed to express the solution as an asymptotic power series. A part of the solution is even determined exactly. At the end of the paper, the attained results are utilized to predict the outcome of the game. The paper concludes with some suggestions and directives for further research. NTIS

NEW MATERIAL FOR HIGH AVERAGE POWER INFRARED GENERATION: QPM-DB GaAs Final Technical Report
Robert L. Byer, Ropbert S. Feigelson, Robert C. Eckardt, Roger K. Route, and Leslie A. Gordon 3 Mar. 1995 30 p
(Contract DAAL03-92-G-0400)
(AD-A292714; GL-5256; ARO-30708.3-PH) Avail: CASI HC A03/MF A01

We have demonstrated diffusion-bonded-stacked GaAs to have good potential for high average power infrared generation. Diffusion bonding is the formation of a crystalline bond between two single-crystal wafers. Quasi phasematching is achieved in a stack of wafers of alternating orientation with the goal of retaining the low loss and high damage threshold of bulk single-crystal material. In this program we have substantially reduced loss per interface from 2% to 0.5% at 2 micrometers. This is adequate for single-pass applications in harmonic, sum and difference frequency generation, but further reduction of loss is required for resonant cavity applications such as optical parametric oscillation. We have performed studies of bonding techniques, surface preparation, optical damage thresholds, and numerical modeling of nonlinear frequency conversion. We are continuing this investigation with new characterization facilities and bonding apparatus and techniques developed in this program. DTIC

EVALUATION OF NONLINEAR STRUCTURAL DYNAMIC RESPONSES USING A FAST-RUNNING SPRING-MASS FORMULATION
A. S. Benjamin, B. S. Altman, and J. D. Gruda 1995 9 p Presented at the International Conference on Computational Engineering Science, Mauna Lani, HI, 30 Jul. - 3 Aug. 1995
(Contract DE-AC04-94AL-85000)
(DE95-008503; SAND-95-0349C; CONF-950788-2) Avail: CASI HC A02/MF A01

In today's world, accurate finite-element simulations of large nonlinear systems may require meshes composed of hundreds of thousands of degrees of freedom. Even with today's fast computers and the promise of ever-faster ones in the future, central processing unit (CPU) expenditures for such problems could be measured in days. Many contemporary engineering problems, such as those found in risk assessment, probabilistic structural analysis, and structural design optimization, cannot tolerate the cost or turnaround time for such CPU-intensive analyses, because these applications require a large number of cases to be run with different inputs. For many risk assessment applications, analysts would prefer running times to be measurable in minutes. There is therefore a need for approximation methods which can solve such problems far more efficiently than the very detailed methods and yet maintain an acceptable degree of accuracy. For this purpose, we have been working on two methods of approximation: neural networks and spring-mass models. This paper presents our work and results to date for spring-mass modeling and analysis, since we are further along in this area than in the neural network formulation. It describes the physical and numerical models contained in a code we developed called STRESS, which stands for 'Spring-mass Transient Response Evaluation for structural Systems'. The paper also presents results for a demonstration problem, and compares these with results obtained for the same problem using PRONTO3D, a state-of-the-art finite element code which was also developed at Sandia. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 39-49 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

The international transatlantic time and frequency transfer experiment was designed by participating laboratories and has been implemented during

1994 to test the international communications path involving a large number of transmitting stations. This paper will present empirically determined clock and time scale differences, time and frequency domain instabilities, and a representative power spectral density analysis. The experiments by the method of co-location which will allow absolute calibration of the participating laboratories have been performed. Absolute time differences and accuracy levels of this experiment will be assessed in the near future. Author

In July 1994, the U.S. Naval Observatory (USNO) Time Service System Engineering Division conducted a field test to establish a baseline accuracy for two-way satellite time transfer synchronization. Three Hewlett-Packard model 5071 high performance cesium frequency standards were transported from the USNO in Washington, DC to Los Angeles, California in the USNO's mobile earth station. Two-Way Satellite Time Transfer links between the mobile earth station and the USNO were conducted each day of the trip, using the Naval Research Laboratory(NRL) designed spread spectrum modem, built by Allen Osborne Associates(AOA). A Motorola six channel GPS receiver was used to track the location and altitude of the mobile earth station and to provide coordinates for calculating Sagnac corrections for the two-way measurements, and relativistic corrections for the cesium clocks. This paper will discuss the trip, the measurement systems used and the results from the data collected. We will show the accuracy of using two-way satellite time transfer for synchronization and the performance of the three HP 5071 cesium clocks in an operational environment.

IMPLEMENTATION OF A STANDARD FORMAT FOR GPS COMMON VIEW DATA
Marc A. Weiss and Claudine Thomas (Bureau International des Poids et Mesures, Sevres, France.) *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 75-88 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

A new format for standardizing common view time transfer data, recommended by the Consultative Committee for the Definition of the Second, is being implemented in receivers commonly used for contributing data for the generation of International Atomic Time. We discuss three aspects of this new format that potentially improve GPS common-view time transfer: (1) the standard specifies the method for treating short term data, (2) it presents data in consistent formats including needed terms not previously available, and (3) the standard includes a header of parameters important for the GPS common-view process. In coordination with the release of firmware conforming to this new format the Bureau International des Poids et Mesures will release future international track schedules consistent with the new standard. EUROPEAN PLANS FOR NEW CLOCKS IN SPACE
Sigfrido M. Leschiutta and Patrizia Tavella *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 101-110 (For primary document see N95-32319 11-70)
Avail: CASI HC A02/MF A04

An outline of the future European space research program where precise clocks are necessary is presented, pointing out how space applications are posing impressive requirements as regards clock mass, power, ruggedness, long life, accuracy and, in some cases, spectral purity. The material presented was gathered in some laboratories; useful information was obtained from the Space Agencies of France (CNES), Germany (DARA) and Italy (ASI), but the bulk is coming from a recent exercise promoted inside ESA (the European Space Agency) and aimed to prefigure space research activities at the beginning of the next millennium. This exercise was called Horizon 2000 plus; the outcomings were summarized in two reports, presented by ESA in may 1994. Precise clocks and time measurements are needed not only for deep-space or out-ward space missions, but are essential tools also for Earth oriented activities. In this latter field, the European views and needs were discussed in October 1994, in a meeting organized by ESA and devoted to Earth Observation problems. By a scrutiny of these reports, an analysis was performed on the missions requiring a precise clock on board and the driving requirements were pointed out, leading to a survey of the necessary PTTI developments that, to some extent, are in the realm of possibility but that pose serious challenges. In this report the use of frequency standards in the satellite navigation systems is not considered. Author

TIME ACTIVITIES AT THE BIPM
Claudine Thomas *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 111-125 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

The generation and dissemination of International Atomic Time, TAI, and of Coordinated Universal Time, UTC, are explicitly mentioned in the list of the principal tasks of the BIPM, recalled in the Comptes Rendus of the 18th Conference Generale des Poids et Mesures, in 1987. These tasks are fulfilled by the BIPM Time Section, thanks to international cooperation with national timing centers, which maintain, under metrological conditions, the clocks used to generate TAI. Besides the current work of data collection and processing, research activities are carried out in order to adapt the computation of TAI to the most recent improvements occurring in the time and frequency domains. Studies concerning the application of general relativity and pulsar timing to time metrology are also actively pursued. This paper summarizes the work done in all these fields and outlines future projects. Author

ANTICIPATED UNCERTAINTY BUDGETS OF PRARETIME AND T2L2 TECHNIQUES AS APPLIED TO ExTRAS
Claudine Thomas, Peter Wolf, Pierre J. M. Uhrich (Laboratoire Primaire du Temps et des Frequences, Paris, France.), W. Schaefer (Stuttgart Univ., Germany.), H. Nau (Deutsche Forschungsanstalt fuer Luft- und Raumfahrt, Oberpfaffenhofen, Germany.), and Christian Veillet (Geomatics Canada, Ottawa, Ontario.) *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 127-139 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

The Experiment on Timing Ranging and Atmospheric Soundings, ExTRAS, was conceived jointly by the European Space Agency, ESA, and the Russian Space Agency, RSA. It is also designated the 'Hydrogen-maser in Space/Meteor-3M project'. The launch of the satellite is scheduled for early 1997. The package, to be flown on board a Russian meteorological satellite includes ultra-stable frequency and time sources, namely two active and auto-tuned hydrogen masers. Communication between the on-board hydrogen masers and the ground station clocks is effected by means of a

microwave link using the modified version for time transfer of the Precise Range And Range-rate Equipment, PRARETIME, technique, and an optical link which uses the Time Transfer by Laser Link, T2L2, method. Both the PRARETIME and T2L2 techniques operate in a two-directional mode, which makes it possible to carry out accurate transmissions without precise knowledge of the satellite and station positions. Due to the exceptional quality of the on-board clocks and to the high performance of the communication techniques with the satellite, satellite clock monitoring and ground clocks synchronization are anticipated to be performed with uncertainties below 0.5 ns (1 sigma). Uncertainty budgets and related comments are presented. Author

PTTI APPLICATIONS AT THE LIMITS OF GPS

Rob J. Douglas and J. Popelar (Geomatics Canada, Ottawa, Ontario.) *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 141-151 (For primary document see N95-32319 11-70)

Avail: CASI HC A03/MF A04

Canadian plans for precise time and time interval services are examined in the light of GPS capabilities developed for geodesy. We present our experience in establishing and operating a geodetic type GPS station in a time laboratory setting, and show sub-nanosecond residuals for time transfer between geodetic sites. We present our approach to establishing realistic standard uncertainties for short-term frequency calibration services over time intervals of hours, and for longer-term frequency dissemination at better than the 10(exp -15) level of accuracy. TIME ASPECTS OF THE EUROPEAN COMPLEMENT TO GPS: CONTINENTAL AND TRANSATLANTIC EXPERIMENTAL PHASES

Pierre J. M. Uhrich, B. Juompan, R. Tourde, M. Brunet (Centre National d'Etudes Spatiales, Toulouse, France.), and J.-F. Dutrey (Centre National d'Etudes Spatiales, Toulouse, France.) *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 153-166 (For primary document see N95-32319 11-70)

Avail: CASI HC A03/MF A04

The CNES project of a European Complement to GPS (CE-GPS) is conceived to fulfill the needs of Civil Aviation for a non-precise approach phase with GPS as sole navigation means. This generates two missions: a monitoring mission - alarm of failure - ,and a navigation mission - generating a GPS-like signal on board the geostationary satellites. The host satellites will be the Inmarsat constellation. The CE-GPS missions lead to some time requirements, mainly the accuracy of GPS time restitution and of monitoring clock synchronization. To demonstrate that the requirements of the CE-GPS could be achieved, including the time aspects, an experiment has been scheduled over the Last two years, using a part of the Inmarsat II F-2 payload and specially designed ground stations based on 10 channels GPS receivers. This paper presents a review of the results obtained during the continental phase of the CE-GPS experiment with two stations in France, along with some experimental results obtained during the transatlantic phase (three stations in France. French Guyana, and South Africa). It describes the synchronization of the monitoring clocks using the GPS Common-view or the C- to L-Band transponder of the Inmarsat satellite, with an estimated accuracy better than 10 ns (1 sigma). NETWORK TIME SYNCHRONIZATION SERVERS AT THE US NAVAL OBSERVATORY

Richard E. Schmidt *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 175-183 (For primary document see N95-32319 11-70)

Avail: CASI HC A02/MF A04

Responding to an increased demand for reliable, accurate time on the Internet and Milnet, the U.S. Naval Observatory Time Service has established the network time servers, tick.usno.navy.mil and tock.usno.navy.mil. The system clocks of these HP9000/747i industrial work stations are synchronized to within a few tens of microseconds of USNO Master Clock 2 using VMEbus IRIG-B interfaces. Redundant time code is available from a VMEbus GPS receiver. UTC(USNO) is provided over the network via a number of protocols, including the Network Time Protocol (NTP) (DARPA Network Working Group Report RFC-1305), the Daytime Protocol (RFC-867), and the Time protocol (RFC-868). Access to USNO network time services is presently open and unrestricted. An overview of USNO time services and results of LAN and WAN time synchronization tests will be presented. Author

CUSTOM TURNKEY TIME AND FREQUENCY SYSTEMS: A STRUCTURED, EXPANDABLE APPROACH

David F. Wright *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 185-190 (For primary document see N95-32319 11-70)

Avail: CASI HC A02/MF A04

Radiocode Clocks Ltd. have developed a Turnkey Time and Frequency Generation and Distribution, System strategy based upon a bus of three, 'core' signals from which any Time code, Pulse rate or Frequency can be produced. The heart of the system is a ruggedized 19 inch, 3U Single Eurocard chassis constructed from machined 10mm aluminum alloy plate and designed to meet stringent Military, Security and Telecommunications specifications. The chassis is fitted with an advanced multilayer backplane with separate ground planes for analog and digital signals ensuring no degradation of low noise frequency references in the proximity of high speed digital pulse transmissions. The system has been designed to be used in three possible configurations: 1) As a stand alone generation and distribution instrument; 2) As a primary distribution unit in a turnkey Time and Frequency system; and 3) As a secondary distribution unit at a remote location from the Turnkey Time and Frequency System providing regeneration of core signals and correction for transmission delays. When configured as a secondary distribution unit the system will continue to provide usable outputs when one, two or even all three of the 'core' signals are lost. The instrument's placement within a system as a possible single point of system failure has required the development of very high reliability translator, synthesizer, phase locked loop and distribution modules together with a comprehensive alarm and monitoring strategy. HIGH RESOLUTION TIME INTERVAL COUNTER

Victor S. Zhang, Dick D. Davis, and Michael A. Lombardi *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 191-200 (For primary document see N95-32319 11-70)

Avail: CASI HC A02/MF A04

In recent years, we have developed two types of high resolution, multi-channel time interval counters. In the NIST two-way time transfer MODEM application, the counter is designed for operating primarily in the interrupt-driven mode, with 3 start channels and 3 stop channels. The intended start and stop signals are 1 PPS, although other frequencies can also be applied to start and stop the count. The time interval counters used in the NIST Frequency Measurement and Analysis System are implemented with 7 start channels and 7 stop channels. Four of the 7 start channels are devoted to the frequencies of 1 MHz, 5 MHz or 10 MHz, while triggering signals to all other start and stop channels can range from 1 PPS to 100 kHz. Time interval interpolation plays a key role in achieving the high resolution time interval measurements for both counters. With a 10 MHz time base, both counters demonstrate a single-shot resolution of better than 40 ps, and a stability of better than 5 x 10(exp -12) (sigma(sub chi)(tau)) after self test of 1000 seconds). The maximum rate of time interval measurements (with no dead time) is 1.0 kHz for the counter used in the MODEM application and is 2.0 kHz for the counter used in the Frequency Measurement and Analysis System. The counters are implemented as plug-in units for an AT-compatible personal computer. This configuration provides an efficient way of using a computer not only to control and operate the counters, but also to store and process measured data. Author

INVESTIGATION INTO THE EFFECTS OF VHF AND UHF BAND RADIATION ON HEWLETT-PACKARD (HP) CESIUM BEAM FREQUENCY STANDARDS
Andrew Dickens *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 201-208 (For primary document see N95-32319 11-70)
Avail: CASI HC A02/MF A04

This paper documents an investigation into reports which have indicated that exposure to VHF and UHF band radiation has adverse effects on the frequency stability of HP cesium beam frequency standards. Tests carried out on the basis of these reports show that sources of VHF and UHF radiation such as two-way hand held police communications devices do cause reproducible adverse effects. This investigation examines reproducible effects and explores possible causes. Author

The SI second of the atomic clock was calibrated to match the Ephemeris Time (ET) second in a mutual four year effort between the National Physical Laboratory (NPL) and the United States Naval Observatory (USNO). The ephemeris time is 'clocked' by observing the elapsed time it takes the Moon to cross two positions (usually occultation of stars relative to a position on Earth) and dividing that time span into the predicted seconds according to the lunar equations of motion. The last revision of the equations of motion was the Improved Lunar Ephemeris (ILE), which was based on E. W. Brown's lunar theory. Brown classically derived the lunar equations from a purely Newtonian gravity with no relativistic compensations. However, ET is very theory dependent and is affected by relativity, which was not included in the ILE. To investigate the relativistic effects, a new, noninertial metric for a gravitated, translationally accelerated and rotating reference frame has three sets of contributions, namely (1) Earth's velocity, (2) the static solar gravity field and (3) the centripetal acceleration from Earth's orbit. This last term can be characterized as a pseudogravitational acceleration. This metric predicts a time dilation calculated to be -0.787481 seconds in one year. The effect of this dilation would make the ET timescale run slower than had been originally determined. Interestingly, this value is within 2 percent of the average leap second insertion rate, which is the result of the divergence between International Atomic Time (TAI) and Earth's rotational time called Universal Time (UT or UTI). Because the predictions themselves are significant, regardless of the comparison to TAI and UT, the authors will be rederiving the lunar ephemeris model in the manner of Brown with the relativistic time dilation effects from the new metric to determine a revised, relativistic ephemeris timescale that could be used to determine UT free of leap second adjustments. THE DEEP SPACE NETWORK STABILITY ANALYZER c32
Julian C. Breidenthal, Charles A. Greenhall, Robert L. Hamell, and Paul F. Kuhnle *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 221-233 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

A stability analyzer for testing NASA Deep Space Network installations during flight radio science experiments is described. The stability analyzer provides realtime measurements of signal properties of general experimental interest: power, phase, and amplitude spectra; Allan deviation; and time series of amplitude, phase shift, and differential phase shift. Input ports are provided for up to four 100 MHz frequency standards and eight baseband analog (greater than 100 kHz bandwidth) signals. Test results indicate the following upper bounds to noise floors when operating on 100 MHz signals: -145 dBc/Hz for phase noise spectrum further than 200 Hz from carrier, 2.5 x 10(exp -15) (tau =1 second) and 1.5 x 10(exp -17) (tau =1000 seconds) for Allan deviation, and 1 x 10(exp -4) degrees for 1-second averages of phase deviation. Four copies of the stability analyzer have been produced, plus one transportable unit for use at non-NASA observatories. Author

Avail: CASI HC A03/MF A04

Time and frequency outputs comparable in quality to the best laboratories have been demonstrated on an integrated system suitable for field application on a global basis. The system measures the time difference between 1 pulse-per-second (pps) signals derived from local primary frequency standards and from a multi-channel GPS C/A receiver. The measured data is processed through optimal SA Filter algorithms that enhance both the stability and accuracy of GPS timing signals. Experiments were run simultaneously at four different sites. Even with large distances between sites, the overall results show a high degree of cross-correlation of the SA noise. With sufficiently long simultaneous measurement sequences, the data shows that determination of the difference in local frequency from an accepted remote standard to better than 1 x 10(exp -14) is possible. This method yields frequency accuracy, stability, and timing stability comparable to that obtained with more conventional common-view experiments. In addition, this approach provides UTC(USNO MC) in real time to an accuracy better than 20 ns without the problems normally associated with conventional common-view techniques. An experimental tracking loop was also set up to demonstrate the use of enhanced GPS for dissemination of UTC(USNO MC) over a wide geographic area. Properly disciplining a cesium standard with a multi-channel GPS receiver, with additional input from USNO, has been found to permit maintaining a timing precision of better than 10 ns between Palo Alto, CA and Washington, DC. MONTE CARLO SIMULATIONS OF PRECISE TIMEKEEPING IN THE MILSTAR COMMUNICATION SATELLITE SYSTEM
James C. Camparo and R. P. Frueholz *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 291-303 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

The Milstar communications satellite system will provide secure antijam communication capabilities for DOD operations into the next century. In order to accomplish this task, the Milstar system will employ precise timekeeping on its satellites and at its ground control stations. The constellation will consist of four satellites in geosynchronous orbit, each carrying a set of four rubidium (Rb) atomic clocks. Several times a day, during normal operation, the Mission Control Element (MCE) will collect timing information from the constellation, and after several days use this information to update the time and frequency of the satellite clocks. The MCE will maintain precise time with a cesium (Cs) atomic clock, synchronized to UTC(USNO) via a GPS receiver. We have developed a Monte Carlo simulation of Milstar's space segment timekeeping. The simulation includes the effects of: uplink/downlink time transfer noise; satellite crosslink time transfer noise; satellite diurnal temperature variations; satellite and ground station atomic clock noise; and also quantization limits regarding satellite time and frequency corrections. The Monte Carlo simulation capability has proven to be an invaluable tool in assessing the performance characteristics of various timekeeping algorithms proposed for Milstar, and also in highlighting the timekeeping capabilities of the system. Here, we provide a brief overview of the basic Milstar timekeeping architecture as it is presently envisioned. We then describe the Monte Carlo simulation of space segment timekeeping, and provide examples of the simulation's efficacy in resolving timekeeping issues. Author

AUTOMATED DELAY MEASUREMENT SYSTEM FOR AN EARTH STATION FOR TWO-WAY SATELLITE TIME AND FREQUENCY TRANSFER
Gerrit deJong and Michel C. Polderman *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 305-317 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

The measurement of the difference of the transmit and receive delays of the signals in a Two-Way Satellite Time and Frequency Transfer (TWSTFT) Earth station is crucial for its nanosecond time transfer capability. Also, the monitoring of the change of this delay difference with time, temperature, humidity, or barometric pressure is important for improving the TWSTFT capabilities. An automated system for this purpose has been developed from the initial design at NMi-VSL. It calibrates separately the transmit and receive delays in cables, amplifiers, upconverters and downconverters, and antenna feeds. The obtained results can be applied as corrections to the TWSTFT measurement when, before and after a measurement session, a calibration session is performed. Preliminary results obtained at NMi-VSL will be shown. Also, if available, the results of a manual version of the system that is planned to be circulated in Sept. 1994 together with a USNO portable station on a calibration trip to European TWSTFT Earth stations. Current practice is to incorporate general empirical models of the troposphere, which depend only on the station height and the elevation of the satellite, in GPS time receivers used for common-view time transfer. Comparisons of these models with a semi-empirical model based on weather measurements show differences of several nanoseconds. This paper reports on a study of tropospheric correction during GPS common-view time transfer over a short baseline of about 700 km, and three long baselines of 6400 km, 9000 km and 9600 km. It is shown that the use of a general empirical model of the troposphere within a region where the climate is similar does not affect time transfer by more than a few hundreds of picoseconds. For the long distance links, differences between the use of a general empirical model and the use of a semi-empirical model reach several nanoseconds. Author

PROSPECTS FOR HIGH ACCURACY TIME DISSEMINATION AND SYNCHRONIZATION USING CODED RADAR PULSES FROM A LOW-EARTH ORBITING SPACECRAFT
Edoardo V. Detoma and C. Dionisio *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 333-345 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

The radar (an acronym for radio detection and ranging) is an instrument developed just before the WW-II to precisely measure the position of an object (target) in space. This is done by emitting a narrow pulse of electromagnetic energy in the RF spectrum, receiving the return echo and measuring the time of flight in the two-way path from the emitter to the target. The propagation delay provides a measure of the range to the target, which is not in itself sufficient to uniquely locate the position of the same in space. However, if a directional antenna is used, the direction of the echo can be assessed by the antenna pointing angles. In this way the position of the target can be uniquely determined in space. How well this can be done is a function of the resolution of the measurements performed (range and direction, i.e.: angles); in turn, the resolution will dictate the time and frequency requirements of the reference oscillator. METAFITTING: WEIGHT OPTIMIZATION FOR LEAST-SQUARES FITTING OF PTTI DATA
Rob J. Douglas and J.-S. Boulanger *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 347-360 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

For precise time intercomparisons between a master frequency standard and a slave time scale, we have found it useful to quantitatively compare different fitting strategies by examining the standard uncertainty in time or average frequency. It is particularly useful when designing procedures which use intermittent intercomparisons, with some parameterized fit used to interpolate or extrapolate from the calibrating intercomparisons. We use the term 'metafitting' for the choices that are made before a fitting procedure is operationally adopted. We present methods for calculating the standard uncertainty for general, weighted least-squares fits and a method for optimizing these weights for a general noise model suitable for many PTTI applications. We present the results of the metafitting of procedures for the use of a regular schedule of (hypothetical) high-accuracy frequency calibration of a maser time scale. We have identified a cumulative series of improvements that give a significant reduction of the expected standard uncertainty, compared to the simplest procedure of resetting the maser synthesizer after each calibration. The metafitting improvements presented include the optimum choice of weights for the calibration runs, optimized over a period of a week or 10 days. Author

METHODOLOGIES FOR STEERING CLOCKS
Harold Chadsey *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 361-368 (For primary document see N95-32319 11-70)
Avail: CASI HC A02/MF A04

One of the concerns of the PTTI community is the coordination of one time scale with another. This is accomplished through steering one clock system to another, with a goal of a zero or constant offset in time and frequency. In order to attain this goal, rate differences are calculated and allowed for by the steering algorithm. This paper will present several of these different methods of determining rate differences. Ideally, any change in rate should not cause the offset to change sign (overshoot) by any amount, but certainly not by as much as its previous absolute value. The advantages and disadvantages of each depend on the user's situation. Author

THE EFFECTS OF CLOCK ERRORS ON TIMESCALE STABILITY
Lee A. Breakiron *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 369-380 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

The weighting scheme for the cesium clocks and hydrogen masers constituting the USNO timing ensemble is reexamined from an empirical standpoint of maximizing both frequency accuracy and timescale uniformity. The utility of a sliding-weight relation between the masers and the cesiums is reaffirmed, but improvement is found if one incorporates inverse Allan variances for sampling times of 12 and 6 hours for the cesiums and masers, respectively, with some dependence on clock model. RELATIVISTIC THEORY FOR SYNTONIZATION OF CLOCKS IN THE VICINITY OF THE EARTH
Peter Wolf and G. Petit *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning

Meeting May 1995 p 381-391 (For primary document see N95-32319 11-70)
Avail: CASI HC A02/MF A04

A well known prediction of Einstein's general theory of relativity states that two ideal clocks that move with a relative velocity, and are submitted to different gravitational fields will, in general, be observed to run at different rates. Similarly the rate of a clock with respect to the coordinate time of some spacetime reference system is dependent on the velocity of the clock in that reference system and on the gravitational fields it is submitted to. For the syntonization of clocks and the realization of coordinate times (like TAI) this rate shift has to be taken into account at an accuracy level which should be below the frequency stability of the clocks in question, i.e. all terms that are larger than the instability of the clocks should be corrected for. We present a theory for the calculation of the relativistic rate shift for clocks in the vicinity of the Earth, including all terms larger than one part in 10(exp 18). This, together with previous work on clock synchronization (Petit & Wolf 1993, 1994), amounts to a complete relativistic theory for the realization of coordinate time scales at picosecond synchronization and 10(exp -18) syntonization accuracy, which should be sufficient to accommodate future developments in time transfer and clock technology. ALLAN DEVIATION COMPUTATIONS OF A LINEAR FREQUENCY SYNTHESIZER SYSTEM USING FREQUENCY DOMAIN TECHNIQUES
Andy Wu *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 393-404 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

Allan Deviation computations of linear frequency synthesizer systems have been reported previously using real-time simulations. Even though it takes less time compared with the actual measurement, it is still very time consuming to compute the Allan Deviation for long sample times with the desired confidence level. Also noises, such as flicker phase noise and flicker frequency noise, can not be simulated precisely. The use of frequency domain techniques can overcome these drawbacks. In this paper the system error model of a fictitious linear frequency synthesizer is developed and its performance using a Cesium (Cs) atomic frequency standard (AFS) as a reference is evaluated using frequency domain techniques. For a linear timing system, the power spectral density at the system output can be computed with known system transfer functions and known power spectral densities from the input noise sources. The resulting power spectral density can then be used to compute the Allan Variance at the system output. Sensitivities of the Allan Variance at the system output to each of its independent input noises are obtained, and they are valuable for design trade-off and trouble-shooting. Author

SVN 9 END-OF-LIFE TESTING **c18**
Gregory E. Hatten *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 405-413 (For primary document see N95-32319 11-70)
Avail: CASI HC A02/MF A04

SVN 9 was a GPS Block I research and development satellite. When it was launched in Jun. 1984, questions regarding the future performance of atomic frequency standards in orbit remained to be answered. In Mar. 1994, after performing for twice its designed life span, SVN 9 was deactivated as a member of the operational GPS satellite constellation. During the next two months, U.S. Air Force and Rockwell personnel performed various tests to determine just how well the atomic frequency standards had withstood ten years in the space environment. The results of these tests are encouraging. With a full constellation of Block II/IIA satellites on orbit, as well as the anticipated launch of the Block IIR satellites, results from the end of life testing will be helpful in assuring the continued success of the GPS program. FIBER OPTIC REFERENCE FREQUENCY DISTRIBUTION TO REMOTE BEAM WAVEGUIDE ANTENNAS **c74**
Malcolm Calhoun, Paul Kuhnle, and Julius Law *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 415-426 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

In the NASA/JPL Deep Space Network (DSN), radio science experiments (probing outer planet atmospheres, rings, gravitational waves, etc.) and very long-base interferometry (VLBI) require ultra-stable, low phase noise reference frequency signals at the user locations. Typical locations for radio science/VLBI exciters and down-converters are the cone areas of the 34 m high efficiency antennas or the 70 m antennas, located several hundred meters from the reference frequency standards. Over the past three years, fiber optic distribution links have replaced coaxial cable distribution for reference frequencies to these antenna sites. Optical fibers are the preferred medium for distribution because of their low attenuation, immunity to EMI/IWI, and temperature stability. A new network of Beam Waveguide (BWG) antennas presently under construction in the DSN requires hydrogen maser stability at tens of kilometers distance from the frequency standards central location. The topic of this paper is the design and implementation of an optical fiber distribution link which provides ultra-stable reference frequencies to users at a remote BWG antenna. The temperature profile from the earth's surface to a depth of six feet over a time period of six months was used to optimize the placement of the fiber optic cables. In-situ evaluation of the fiber optic link performance indicates Allan deviation on the order of parts in 10(exp -15) at 1000 and 10,000 seconds averaging time; thus, the link stability degradation due to environmental conditions still preserves hydrogen maser stability at the user locations. This paper reports on the implementation of optical fibers and electro-optic devices for distributing very stable, low phase noise reference signals to remote BWG antenna locations. Allan deviation and phase noise test results for a 16 km fiber optic distribution link are presented in the paper. Author

LASER RETROREFLECTOR EXPERIMENT ON NAVSTAR 35 AND 36 **c36**
E. C. Pavlis and Ronald L. Beard (Naval Research Lab., Washington, DC.) *In its* The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 427-441 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

In GPS one of the primary errors contributing to positioning inaccuracy is the performance of the on-board atomic clock. To determine and predict the performance of this atomic clock has been a problem due to the ambiguity of the orbital position error and clock uncertainty in the Radio Frequency (RF) tracking of the navigation signals. The Laser Retroreflector Experiment (LRE) on-board NAVSTAR 35 and 36 provides a means of separating these ambiguous errors by enabling highly precise and accurate satellite positions to be determined independently of the RF signals. The results of examining onboard clock behavior after removing the orbital position signatures will be discussed. GPS RF tracking data from various DOD and other sites are used to reconstruct the onboard clock data and examine the clock behavior. From these data, the effects of clock performance on GPS positioning performance can examined. Author

(T2L2) TIME TRANSFER BY LASER LINK **c36**
Christian Veillet and Patricia Fridelance *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 443-453 (For primary document see N95-32319 11-70)
Avail: CASI HC A03/MF A04

T2L2 (Time Transfer by Laser Link) is a new generation time transfer experiment based on the principles of LASSO (Laser Synchronization from Synchronous Orbit) and used with an operational procedure developed at OCA (Observatoire de la Cote d'Azur) during the active intercontinental phase of LASSO. The hardware improvements could lead to a precision better than 10 ps for time transfer (flying clock monitoring or ground based clock comparison). Such a package could fly on any spacecraft with a stable clock. It has been developed in France in the frame of the PHARAO project (cooled atom clock in orbit) involving CNES and different laboratories. But T2L2 could fly on any spacecraft carrying a stable oscillator. A GPS satellite would be a good candidate, as T2L2 could allow to link

the flying clock directly to ground clocks using light, aiming to important accuracy checks, both for time and for geodesy. Radioastron (a flying VLBI antenna with a H-maser) is also envisioned, waiting for a PHARAO flight. The ultimate goal of T2L2 is to be part of more ambitious missions, as SORT (Solar Orbit Relativity Test), aiming to examine aspects of the gravitation in the vicinity of the Sun. Author

SATELLITE TEST OF THE ISOTROPY OF THE ONE-WAY SPE ED OF LIGHT USING ExTRAS
Peter Wolf *In* NASA. Goddard Space Flight Center, The 26th Annual Precise Time and Time Interval (PTTI) Applications and Planning Meeting May 1995 p 455-463 (For primary document see N95-32319 11-70)
Avail: CASI HC A02/MF A04

A test of the second postulate of special relativity, the universality of the speed of light, using the ExTRAS (Experiment on Timing Ranging and Atmospheric Sounding) payload to be flown on board a Russian Meteor-3M satellite (launch date January 1997) is proposed. The propagation time of a light signal transmitted from one point to another without reflection would be measured directly by comparing the phases of two hydrogen maser clocks, one on board and one on the ground, using laser or microwave time transfer systems. An estimated uncertainty budget of the proposed measurements is given, resulting in an expected sensitivity of the experiment of delta c/c is less than 8xl0(exp -10) which would be an improvement by a factor of approximately 430 over previous direct measurements and by a factor of approximately 4 over the best indirect measurement. The proposed test would require no equipment additional to what is already planned and so is of inherently low-cost. It could be carried out by anyone having access to a laser or microwave ground station and a hydrogen maser. Author

METHOD AND SYSTEM FOR SUPPRESSING NOISE INDUCED IN A FLUID MEDIUM BY A BODY MOVING THERETHROUGH Patent
Richard A. Katz, inventor (to Navy) 25 Oct. 1994 18 p Filed 2 Sep. 1993
(AD-D017339; US-Patent-5,359,663; US-Patent-Appl-SN-117513; US-Patent-Class-381-71) Avail: US Patent and Trademark Office

A method of detecting the onset of turbulence in connection with a body moving through a fluid medium and reducing turbulence noise acoustic sensor systems carried thereby. First, the body is supplied with sensors each for generating a signal suitable for measuring amplitude of pressure fluctuations of the medium proximate a region of said sidewall of the body in at least a region of the body in which turbulence is expected to occur. During a reference stage during which the body moves through the fluid medium when it is known that turbulence is occurring around at least a portion of said body the sensors each generate reference temporal pressure data representing fluctuations in pressure of the fluid medium around said body. In response to reference temporal pressure data representing by sensors in a turbulence zone at which turbulence is occurring and sensors in a transition zone at which turbulence zone and a laminar flow zone, method-of-delay phase portraits are generated for a progression selected delay intervals. During an operational stage, the signals from the sensors are filtered to generate a portion representing the turbulence due to motion of the body through a portion representing signals from external acoustic signal sources, and the turbulence signal portion is used to generate signals of appropriate phase which are injected into the medium to reduce the turbulence noise signals. THERMOACOUSTIC SOUND GENERATOR Patent
Thomas B. Gabrielson, inventor (to Navy) 29 Nov. 1994 10 p Filed 31 May 1991
(AD-D017342; US-Patent-5,369,625; US-Patent-Appl-SN-709901; US-Patent-Class-367-140) Avail: US Patent and Trademark Office

A submersible acoustic generator for projection of sound waves into a body of water comprises a tubular resonator, open at its lower end and closed at its upper end, and having a multiple-plate thermoacoustic stack located near the upper end between a pair of heat exchangers which set up a temperature gradient in the stack. The upper heat exchanger is heated by a chemical fuel, and the lower heat exchanger is cooled by the surrounding water. The resonator is gas-filled, and the wavelength of the oscillations produced is approximately twice the length of the resonator. A portion of the resonator tube can be surrounded by a coaxial tube which serves as an impedance matching stub. The stack plates can be made anisotropic by means of embedded copper wires. In alternative versions of the apparatus, the resonator can have two stacks, one near the open end and the other near the closed end, and the temperature gradient in the stack can be established cryogenically. DESIGN OF SYSTEMS FOR ACTIVE SOUND CONTROL Ph.D. Thesis
N. J. Doelman 2 Dec. 1993 228 p Sponsored by Stichting voor de Technische Wetenschappen
(PB95-197869; ISBN-90-9006731-0) Copyright Avail: CASI HC A11/MF A03

In this thesis the complete trajectory of designing a control system for active sound reduction is described. Starting with the fundamental acoustical theory, the design deals with discrete source and sensor distributions, discrete acoustic processes, control strategies and, finally, a large number of practical experiments. The acoustical essence of active sound reduction is based on a distribution of Huygens' sources, that has the potential to reconstruct a primary sound field with equal strength but opposite phase. A continuous distribution of monopoles and dipoles on a closed surface is shown to be the ideal anti-sound source distribution. It is capable of completely attenuating a sound field inside the closed surface. The acoustic part of the design is completed by addressing the distribution of a limited number of sensors. Two types of sensors are required. First, a distribution of detection sensors measures the incident primary sound field. Second, a distribution of error sensors measures the residual sound field. Given a source-sensor distribution, a digital control strategy has to be designed. A first step in this is to model the discrete acoustic processes or transfer functions. It is demonstrated that a discrete acoustic process is likely to have a non-minimum phase behavior. This has to be accounted for in the design of the controller. NTIS

RAY TRACE MODEL OF SOUND PROPAGATION IN RANGE DEPENDENT MEDIA
T. Serenander Jun. 1994 63 p
(PB95-211751; FOA-C-20982-2.2) Avail: CASI HC A04/MF A01

This report treats numerical calculation of sound propagation in range dependent media when the frequency is sufficiently high for classical ray theory to be applicable. The sound field is then described by ray paths, that can be computed numerically by solving a system of ordinary differential equations (ODE's). The ODE's are formulated in terms of the sound speed c(r) of the medium as function of position r. Two methods are studied for constructing smooth approximations c tilde(r) of functions c(r) that vary in two dimensions (range and depth). In both methods, c tilde(r) is represented by B-splines and is computed from given sparsely located observed values of c(r). This representation of c(r) is implemented as an extension of a ray-tracing program which previously could handle range-independent cases only. The program solves the ODE's of the ray paths by an implicit linear multistep method with adaptively chosen stepsize and order. The program is written in FORTRAN and IS-Lab. Examples of ray trace calculations are presented. Ray patterns produced with realistic range dependent velocity files are compared with those obtained using range independent approximations. As a last example we study the propagation of a ray fan in a channel with sinusoidal bottom depth. NTIS

US-Patent-Class-367-7) Avail: US Patent and Trademark Office

A detector array of operationally independent transducers is deployed in a medium such as water is described. Each transducer generates an electrical signal across independent first and second electrodes corresponding to impinging acoustic energy. Each of the positions in the detector array is identified in sequence along with the identification of a corresponding pixel position or display position in a display structure. A first multiplexer connects to all the first electrodes and a second multiplexer connects to all the second electrodes to enable the identification circuit to select corresponding electrodes for each detector position. A single amplifier circuit couples the signals front the multiplexer to a circuit for controlling the illumination of a selected display position. DTIC

METHOD AND APPARATUS FOR LOCATING AN ACOUSTIC SOURCE Patent
Bruce J. Bates, inventor (to Navy) and Susan M. Bates, inventor (to Navy) 18 Oct. 1994 15 p Filed 22 Oct. 1993
(AD-D017347; US-Patent-5,357,484; US-Patent-Appl-SN-147237;
US-Patent-Class-367-116) Avail: US Patent and Trademark Office

An apparatus and method for determining the range and depth to an acoustic source from a sampling site in a medium are described. A linear array of pressure transducers monitors the acoustic field produced by the acoustic source. A measurement processor utilizes the measured acoustic field to produce an initial field condition for each member of the array. An environmental model include environmental data in the form of acoustically pertinent field condition and the acoustically pertinent variables to produce, for each incremental range and depth, an amplitude function. An index processor normalizes the amplitude functions for each incremental range and depth, and an index extreme value processor selects the amplitude function with the maximum amplitude. The range and depth of that extreme value amplitude function is used to determine the range and depth for the acoustic source. DTIC

US-Patent-Class-364-574) Avail: US Patent and Trademark Office

A system for providing an iterative method of assessing accuracy of selected models of physical phenomena and for determining selection of alternate models in response to a data sequence in the presence of noise is described. Initially, a residual sequence is generated reflecting difference values between in response to said data sequence and an expected data sequence as would be represented by a selected model. Feature estimate values of a plurality of predetermined data features in the residual sequence are then generated. In response to the feature estimate values, a threshold value is generated for each feature at an estimated ratio of data to noise. Probability values are generated in response to the threshold value, representing the likelihood that the feature exists in the data sequence, does not exist in the data sequence, and that the existence or non-existence in the data sequence is not determinable. Finally, a model is selected in response to the probability values for use during a subsequent iteration. DTIC

FAR FIELD ACOUSTIC RADIATION REDUCTION Patent
Michael A. Sartori, inventor (to Navy) and Joseph A. Clark, inventor (to Navy) 10 Jan. 1995 6 p Filed 30 Sep. 1993
(AD-D017452; US-Patent-5,381,381; US-Patent-Appl-SN-128411;
US-Patent-Class-367-1) Avail: US Patent and Trademark Office

A system and method are provided to reduce a structure's far field acoustic radiation signature. A plurality of acoustic sensors are positioned in the acoustic near field of the structure for measuring the near field acoustic radiation of the structure. A programmable controller generates a prediction of the structure's far field acoustic radiation signature using the near field acoustic radiation. The prediction is then used to generate a noise control signal applied to a plurality of acoustic radiators suspended within the structure. The radiators convert substantially all of the noise control signal to airborne acoustic energy within the structure. DTIC

NOISE SIGNAL PROCESSOR Patent
Lawrence C. Pharo, Jr., inventor (to Navy) and John J. Portelli, inventor (to Navy) 4 Oct. 1994 11 p Filed 13 May 1982
(AD-D017430; US-Patent-5,353,260; US-Patent-Appl-SN-378444;
US-Patent-Class-367-135) Avail: US Patent and Trademark Office

This patent discloses an apparatus for providing a direct quantitative readout of the amplitudes of various frequency lines that constitute the envelope of an amplitude-modulated broadband noise signal. A selected band of carrier frequencies is fed to an AGC circuit that provides a constant-input signal amplitude to a demodulator for a period of time that is greater than the period of the lowest frequency of the modulating signal for detection. The detected signal is fed to a spectrum analyzer for the direct reading of the percent modulation. DTIC

SOLUTION OF THE THREE-DIMENSIONAL HELMHOLTZ EQUATION WITH NONLOCAL BOUNDARY CONDITIONS
Steve L. Hodge (Virginia Consortium for Engineering and Science, Hampton, VA.), William E. Zorumski, and Willie R. Watson May 1995 40 p
(RTOP 505-63-50-25)
(NASA-TM-110174; NAS 1.15:110174) Avail: CASI HC A03/MF A01

The Helmholtz equation is solved within a three-dimensional rectangular duct with a nonlocal radiation boundary condition at the duct exit plane. This condition accurately models the acoustic admittance at an arbitrarily-located computational boundary plane. A linear system of equations is constructed with second-order central differences for the Helmholtz operator and second-order backward differences for both local admittance conditions and the gradient term in the nonlocal radiation boundary condition. The resulting matrix equation is large, sparse, and non-Hermitian. The size and structure of the matrix makes direct solution techniques impractical; as a result, a nonstationary iterative technique is used for its solution. The theory behind the nonstationary technique is reviewed, and numerical results are presented for radiation from both a point source and a planar acoustic source. The solutions with the nonlocal boundary conditions are invariant to the location of the computational boundary, and the same nonlocal conditions are valid for all solutions. The nonlocal conditions thus provide a means of minimizing the size of three-dimensional computational domains. Author

CALCULATIONS OF THE SOUND SCATTERING FROM FLUID-FILLED SPHERICAL SHELL SONAR TARGETS
Mark Readhead Jan. 1995 71 p Original contains color illustrations
(DSTO-RR-0020; AR-008-995) Avail: Issuing Activity (DSTO Aeronautical and Maritime Research Lab., GPO Box 4331, Melbourne, Victoria 3001, Australia)

The theory of the sound pressure scattered from a fluid-filled spherical shell immersed in a second fluid is developed. An arbitrary combination of fluids may be used to fill the shell, and both the sound source and the receiver may be in the near field. The theory is used to calculate the pressure field in both the interior and exterior fluids and is extended to determine the time-dependence of the reflected signal and the target strength. The dependence of these quantities as a function of frequency and pulse type; shell material, diameter and wall thickness; fluid combination; temperature; and distance of the receiver from the sphere is examined, and is shown to be sensitive to most of these parameters. The performance of spheres filled with a Freon-113(tm)-ethanol or Fluorinert FC-72(tm)-n-hexane mixture is considered. Author

ADAPTIVE OPTICS DESIGN FOR THE ADVANCED ELECTRO-OPTICAL SYSTEM (AEOS) Final Report, Mar. 1993 - Mar. 1994
David W. Tyler and Amy E. Prochko Nov. 1994 60 p Prepared in

cooperation with Schafer Associates, Inc.
(Contract F29601-90-C-0068)
(AD-A293972; PL-TR-94-1043) Avail: CASI HC A04/MF A01

We develop an algorithm to guide the use of computer simulations in the design of application-specific adaptive optics (AO) systems. We then use this method to specify the number of deformable-mirror actuators and closed-loop bandwidth for the Advanced Electro-Optical System (AEOS) telescope AO system. To develop the algorithm we present analysis to show the normalized on-axis intensity can be minimized for a given AO configuration by selecting an optimum imaging wavelength. This wavelength minimizes the combined effects of diffraction, which increases with wavelength, and residual (post-compensation) phase aberration, which decreases as wavelength increases. We also show that the closed-loop AO bandwidth minimizing the sum of wavefront sensor noise error and control loop lag error is independent of wavelength. This allows the optimum bandwidth-wavelength combination for any AO configuration to be calculated non-iteratively in two steps. We describe a high-fidelity computer simulation and measures of merit used to select from among four candidate configurations. Finally, we present simulation results used to select the AEOS adaptive optics configuration and recommend the AEOS system use approximately 700 actuators with a maximum closed-loop bandwidth of at least 400 Hz. THE EFFECTS OF LARGE AND SMALL SCALE TURBULENCE ON SOUND PROPAGATION IN THE ATMOSPHERE
John M. Noble and Harry J. Auvermann Mar. 1995 64 p
(AD-A293657; ARL-TR-565) Avail: CASI HC A04/MF A01

Propagation of acoustic waves in the atmosphere is affected by several mechanisms. Two of the effects are the scattering of sound by small-scale atmospheric turbulence and fluctuation of the speed of sound gradients by the passage of large-scale atmospheric turbulence. Small- and large-scale atmospheric turbulence causes the acoustic waves to be altered by different mechanisms. Until recently, the majority of work in turbulence effect on acoustics has concentrated on the small-scale turbulence regime of the inertial subrange of the Kolmogorov spectrum. Earlier small-scale turbulence models have concentrated on the statistical-based work of Tatarski. Current turbulence models deal more with the structural nature of the turbulence because the statistical approach does not account for all of the turbulence effects being measured during acoustic propagation experiments. The large-scale turbulence problem cannot be handled very well with a statistical approach to atmospheric turbulence because the regime of the large-scale turbulence extends into the energy containing subrange or sometimes referred to as the source region. This report discusses the current and past turbulence models used to treat the effect of small- and large-scale turbulence on atmospheric acoustic propagation. DTIC

FRACTIONAL DELAY WAVEGUIDE MODELING OF ACOUSTIC TUBES
V. Vaelimaeki 1994 135 p
(PB95-206637; ISBN-951-22-2158-6) Avail: CASI HC A07/MF A02

The theme of this work is computational modeling of acoustic tubes. The models are intended to be used in a sound synthesizer based on physical modeling. Such a synthesizer could be used producing realistic sounds of, e.g., woodwind instruments or the human voice. This work deals with digital waveguide modeling of acoustic tubes, such as bores of musical woodwind instruments or the human vocal tract. The acoustic tube systems considered in this work are those consisting of a straight cylindrical or conical tube or of concatenated cylindrical or conical tube sections. Also, the joint of three tube sections is studied. Of special interest for our application is a junction where a side branch is connected to a cylindrical tube as it is needed in the simulation of finger holes of wood-wind instruments. All of the cylindrical tube models are described for both pressure and volume velocity. In the case of conical bores, only pressure waves are considered as models for volume velocity waves are more complicated. The basic waveguide models are extended by employing the concept of fractional delay, which means a delay smaller than a unit delay. The fractional delays are implemented using bandlimited interpolation. Applying fractional delay filtering techniques, a spatially discretized waveguide model is turned into a spatially continuous one. This implies that the length of the digital waveguide can be adjusted as accurately as required, and a change of the impedance of a waveguide may occur at any desired point between sampling points. The authors call this kind of system a fractional delay waveguide filter (FDWF). It is a discrete-time structure but a spatially continuous model of a physical system. NTIS

THE MECHANISM OF PARTICLE PRODUCTION PROCESS IN HADRON-NUCLEON COLLISIONS
Z. Strugalski 1994 10 p
(DE95-613727; JINR-E-1-94-294) Avail: CASI HC A02/MF A01 (US Sales Only)

The mechanism of particle production process in hadron-nucleon collisions has been studied experimentally, using intranuclear detector. Particles are created via intermediate objects decaying into commonly observed resonances and particles after the lifetime more than about 10(sup 22) s. The appearance of the well-collimated spurts of particles, or jets, in the final state, and of the large transverse momenta are therefore naturally a simple and indispensable consequence of such mechanism of the particle production. (Contract F49620-92-J-0072)
(AD-A290895; AFOSR-95-0068TR) Avail: CASI HC A03/MF A01

Flowing afterglow, flow-drift, and selected ion flow tube techniques have been coupled with laser-induced fluorescence detection to explore the chemistry and dynamics of gas phase ion-molecule interactions. The vibrational product state distributions of proton transfer and charge transfer reactions have been characterized. The competition between reaction and quenching has been probed for the interactions of vibrationally excited molecular nitrogen cation with ten neutral reagents. These reactions exhibit a rich and diverse chemistry; for example, reaction with molecular hydrogen is independent of the vibrational state of the nitrogen cation, whereas the exothermic reaction with krypton shows increasing reactivity as the excitation is systematically increased over the five lowest vibrational levels. Single frequency laser probing has been employed to characterize of the potential parameters and velocity correlations for barium cation drifted in argon, to measure the mobility of vibrationally and rotationally excited molecular ions, to intercompare mobilities measured by laser-induced fluorescence with those from standard ion shutter techniques and to probe the velocity dependence of ion alignment. MAGNETO-OPTICAL TRANSMISSION-REFLECTION BEAM SPLITTER FOR MULTI-LEVEL ATOMS
John E. Murphy, Peter Goodman, and Andrei I. Sidorov (Academy of Sciences, USSR, Moscow, USSR.) 1994 18 p
(DE95-616267; UM-P-94/60) Avail: CASI HC A03/MF A01 (US Sales Only)

An atomic de Broglie wave beam splitter is proposed. The interaction of multi-level atoms (J(g) = 1 - J(e) = 0) with a laser beam in the presence of a static magnetic field leads to the partial transmission and reflection of the atomic beam. The coherent splitting of the atomic beam occurs due to non-adiabatic transitions between different dressed states in the vicinity of avoided crossings. The transition probabilities and populations of split beams are dependent on the value of the magnetic field, laser detuning, and the ratio between different polarization components in the laser beam. For optimal conditions the population of each of the two transmitted and two reflected beams is 25%. For cooled atoms it is possible to obtain splitting angles of 80 mrad. The effect of spontaneous emission during the atom-light interaction was estimated and for a reasonable detuning losses were reduced to less than 10%. DOE

COMPLEX CONJUGATE PAIRS IN STATIONARY STURMIANS
P. J. Dortmans, L. Canton, G. Pisent, and K. Amos (Melbourne Univ., Parkville, Australia.) 1994 8 p
(DE95-616279; UM-P-93/112) Avail: CASI HC A02/MF A01 (US Sales Only)

Sturmian expansions enable a simply accurate separable specification of two nucleon matrices based upon realistic two nucleon interactions. Sturmian eigenstates specified by stationary scattering boundary conditions are particularly useful in that context, and they can be calculated by solving a generalized eigenvalue equation using real and symmetric matrices. In general, the spectrum of such an equation may contain complex eigenvalues. But to each complex eigenvalues there is a corresponding conjugate partner. In studies using realistic two nucleon potentials, and in certain positive energy intervals, these complex conjugated pairs indeed appear in the Sturmian spectrum. However, it is demonstrated that it is possible to recombine the complex conjugate pairs and corresponding states into a new, (and useful) pair of real eigenvalues and eigenstates with which of effect separable expansions of the (real) two nucleon reactance matrices. EFFECTIVE LAGRANGIAN APPROACH TO THE FERMION MASS PROBLEM
D. S. Shaw and R. R. Volkas 1994 22 p
(DE95-616316; UM-P-93/81; OZ-93/21) Avail: CASI HC A03/MF A01 (US Sales Only)

An effective theory is proposed, combining the standard gauge group SU(3)(sub C) direct-product SU(2)(sub L) direct-product U(1)(sub Y) with a horizontal discrete symmetry. By assigning appropriate charges under this discrete symmetry to the various fermion fields and to (at least) two Higgs doublets, the broad spread of the fermion mass and mixing angle spectrum can be explained as a result of suppressed, non-renormalizable terms. A particular model is constructed which achieves the above while simultaneously suppressing neutral Higgs-induced flavor-changing processes. DOE

PHENOMENOLOGY OF THE TWO HIGGS DOUBLET SECTOR OF A QUARK-LEPTON SYMMETRIC MODEL
C. C. Lassig and R. R. Volkas Mar. 1994 19 p
(DE95-616337; UM-P-94/21; OZ-94/8) Avail: CASI HC A03/MF A01 (US Sales Only)

In the simplest examples of models with a discrete quark-lepton symmetry, an electroweak symmetry braking sector with more than one

Higgs doublet is necessary to obtain the correct mass relations between quarks and leptons. A two Higgs doublet model version has flavor-nonconserving Yukawa couplings, which are proportional to the masses of the quark-lepton symmetric partners of the fermions. The main focus of this paper will be on flavor-changing leptonic decays, in particular those of muons since these give the most opportunity for experimental investigation. The neutral Higgs mediated decay mu(sup -) yields e(sup -) e(sup +)e(sup -) will be investigated at tree-level, as will the charged-Higgs contribution to the decay mu(sup -) yields upsilon(sub mu) e(sup -) upsilon (sup -)bar (sub e). A one-loop calculation of the process mu yields e gamma will be performed. This will lead on to an examination of the effect on the muon anomalous magnetic moment. Finally, the effect of the quark-lepton symmetric 2HDM contribution to b yields s gamma will briefly be considered. DOE

DENSITY DEPENDENT EFFECTIVE INTERACTIONS
P. J. Dortmans and K. Amos 1994 21 p
(DE95-616348; UM-P-93/84) Avail: CASI HC A03/MF A01 (US Sales Only)

An effective nucleon-nucleon interaction is defined by an optimal fit to select on and half-off of the energy shell t- and g-matrices determined by solutions of the Lippmann-Schwinger and Brueckner-Bethe-Goldstone equations with the Paris nucleon-nucleon interaction as input. As such, it is seen to better reproduce the interaction on which it is based than other commonly used density dependent effective interactions. The new (medium modified) effective interaction, when folded with appropriate density matrices, has been used to define proton-(sup 12)C and proton-(sup 16)O optical potentials. With them elastic scattering data are well fit and the medium effects identifiable. DOE

HADRONIC PRODUCTION OF S-WAVE AND P-WAVE CHARMED BEAUTY MESONS VIA HEAVY QUARK FRAGMENTATION
K. Cheung and Tzu Chiang Yuan (California Univ., Davis, CA.) Feb. 1995 29 p
(Contract DE-FG03-93ER-40757)
(DE95-008737; DOE/ER-40757/060; UCD-95-4) Avail: CASI HC A03/MF A01

At hadron colliders the dominant production mechanism of (bar-b c) mesons with large transverse momentum is due to parton fragmentation. The authors compute in a model-independent way the production rates and transverse momentum spectra for S-wave and P-wave (bar-b c) mesons at the Tevatron via the direct fragmentation of the bottom antiquark as well as the Altarelli-Parisi induced gluon fragmentation. Since all the radially and orbitally excited (bar-b c) mesons below the BD flavor threshold will cascade into the pseudoscalar ground state B(sub c) through electromagnetic and/or hadronic transitions, they all contribute to the inclusive production of B(sub c). The contributions of the excited S-wave and P-wave states to the inclusive production of B(sub c) are 58 and 23%, respectively, and hence significant. DOE

STRUCTURAL INVESTIGATION OF XENON ION-BEAM-IRRADIATED GLASSY CARBON
D. G. McCulloch (Monash Univ., Clayton, Australia.), S. Prawer, and A. Hoffman (Technion - Israel Inst. of Tech., Haifa, Israel.) 1994 38 p
(DE95-616777; UM-P-94/52) Avail: CASI HC A03/MF A01 (US Sales Only)

Raman spectroscopy, cross-sectional transmission microscopy, and electron energy loss spectroscopy have been used to monitor the ion beam induced transformation in glassy carbon irradiated with 320 keV xenon ions to doses between 5 x 10(exp 12) and 6 x 10(exp 16) ions/cm(exp 2). It was found that the ion beam amorphizes the glassy carbon structure, the amorphization is accompanied by a compaction of the glassy carbon from an initial density of 1.55 to 2.2 +/- 0.2 g/cm(exp 3) and that approximately 15% of the graphite-like bonds in glassy carbon are converted to diamond-like bonds in the amorphization process. The transformation occurs in two distinct stages as a function of ion dose. For damage levels up to 0.2 dpa the effect of ion beam is to decrease the average graphitic crystallite size. Above 0.2 dpa, disorder in bond length and bond angle away from ideal graphitic threefold coordination occurs leading to complete amorphization at high doses. The amorphization, compaction and presence of approximative 15% sp(exp 3) bonds in the implanted layer of glassy carbon results in surface layer which is significantly more resistant to abrasion than as-grown glassy carbon. DOE

INELASTIC PLASMON AND INTER-BAND ELECTRON-SCATTERING POTENTIALS FOR SI FROM DIELECTRIC MATRIX CALCULATIONS
T. W. Josefsson and A. E. Smith (Monash Univ., Clayton, Australia.) 1994 24 p
(DE95-616778; UM-P-94/55) Avail: CASI HC A03/MF A01 (US Sales Only)

Inelastic scattering of electrons in a crystalline environment may be represented by a complex non-Hermitian potential. Complete generalized expressions for this inelastic electron scattering potential matrix, including virtual inelastic scattering, are derived for outer-shell electron and plasmon excitations. The relationship between these expressions and the general anisotropic dielectric response matrix of the solid is discussed. These generalized expressions necessarily include the off-diagonal terms representing effects due to departure from translational invariance in the interaction. Results are presented for the diagonal back structure dependent inelastic and virtual inelastic scattering potentials for Si, from a calculation of the inverse dielectric matrix in the random phase approximation. Good agreement is found with experiment as a function of incident energies from 10 eV to 100 keV. Anisotropy effects and hence the interaction delocalization represented by the off-diagonal scattering potential terms are found to be significant below 1 keV. DOE

THE EFFECT OF A NON-HERMITIAN CRYSTAL POTENTIAL ON THE SCATTERING MATRIX IN REFLECTION ELECTRON DIFFRACTION
A. E. Smith (Monash Univ., Clayton, Australia.) and T. W. Josefsson 1994 13 p
(DE95-616779; UM-P-94/56) Avail: CASI HC A03/MF A01 (US Sales Only)

An extension to include general inelastic scattering effects is developed for the case of reflection electron diffraction scattering from surfaces. In this extension of work by Lynch and Moodie, it is shown how the resultant non-Hermitian matrix problem can be recast in a form that is suitable for computation. In particular, a computational method is outlined based on techniques developed by Eberlein for matrix diagonalization using complex rotations and shears. The resultant methods are applied to the problem of convergent beam RHEED. DOE

CONFRONTING LEFT-RIGHT SYMMETRIC MODELS WITH ELECTROWEAK PRECISION DATA AT THE Z PEAK
A. Pilaftsis Jan. 1995 26 p
(PB95-208054; RAL-95-014) Avail: Issuing Activity (National Technical Information Service (NTIS))

In view of the recent and future electroweak precision data accumulated at LEP and SLC, we systematically analyze possible new physics effects that may occur in the leptonic sector within the context of SU(2)(sub R) x SU(2)(sub L) x U(1)(sub B-L) theories. It is shown that nonobservation of flavor-violating Z-boson decays, lepton universality in the decays Z to l(l bar), and universality of lepton asymmetries at the Z peak form a set of complementary observables, yielding severe constraints on the parameter space of these theories. Contributions of new-physics effects to R(sub b) = Gamma(Z to b(b bar))/Gamma(Z to hadrons) are found to give interesting mass relations for the flavor-changing Higgs scalars present in these models. NEW TENSOR INTERACTIONS IN MICRON-DECAY
M. V. Chizhov (Sofia Univ., Bulgaria.) 1994 6 p
(DE95-613760; JINR-E-2-94-254) Avail: CASI HC A02/MF A01 (US Sales Only)

The most general form of the Hamiltonian for the muon decay is presented. We assume that it arises as a result of the exchange of intermediate bosons with a momentum q and naturally should depend on this momentum. This allows us to introduce two additional coupling constants for the tensor interactions which give rise to new parameters in the energy spectrum of positrons. The experimental consequences of such a generalization are discussed. DOE

SEMICONDUCTOR NANOCRYSTALS FORMED IN SiO2 BY ION IMPLANTATION
J. G. Zhu, C. W. White, J. D. Budai, S. P. Withrow, and Y. Chen Nov. 1994 8 p Presented at the 1994 Fall Meeting of the Materials Research Society (MRS), Boston, MA, 28 Nov. - 2 Dec. 1994
(Contracts DE-AC05-84OR-21400; DE-AC05-76OR-00033)
(DE95-008900; CONF-941144-98) Avail: CASI HC A02/MF A01

Nanocrystals of group 4 (Si, Ge and SiGe), 3-4 (GaAs), and 2-6 (CdSe) semiconductor materials have been fabricated inside SiO2 by ion implantation and subsequent thermal annealing. The microstructure of these nanocrystalline semiconductor materials has been studied by transmission electron microscopy (TEM). The nanocrystals form in near-spherical shape with random crystal orientations in amorphous SiO2. Extensive studies on the nanocrystal size distributions have been carried out for the Ge nanocrystals by changing the implantation doses and the annealing temperatures. Remarkable roughening of the nanocrystals occurs when the annealing temperature is raised over the melting temperature of the implanted semiconductor material. Strong red photoluminescence peaked around 1.67 eV has been achieved in samples with Si nanocrystals in SiO2. DOE
